## PREFACE.

---

THE remarks which stand in the position of "Preface" to a volume consisting of the aggregated numbers of a weekly journal, forming a year's issue, are necessarily the last words written in that volume, and afford the Editor opportunity, if need be, for observations, explanatory or qualifying, in regard to the work of the year. In the Volume just concluded we have, fortunately, nothing to qualify or explain. Our record of a year's progress in the now comprehensive field of photography, and the aids we have furnished to that progress—by the pens of our contributors and correspondents, and by our own—are before the reader, and furnish their own best explanation.

It would be now somewhat late in the day to enlarge on the aids to photographic progress furnished by photographic journalism. The unprecedented rapidity of the progress of the art, the universality of its practice throughout the world, its singular fecundity of application, and the rare perfection to which—in many respects, at least—it has attained in little more than a quarter of a century, are due, it cannot be doubted, in a great measure to the fact that greater facilities and inducements for the communication and interchange of ideas and for the diffusion of information, by means of a special press, have existed in connection with this art, than have, perhaps, ever existed in connection with any other art or science. In writing the final words of the Twelfth Volume of the first weekly journal devoted to photography, these reflections naturally occur. During the period of time which has elapsed since the PHOTOGRAPHIC NEWS was established, photographic journalism has become more extended and active: many other journals devoted to the art have sprung into existence, and, after flourishing a short time, have passed away and been forgotten; whilst this journal—the Editor makes the assertion with much gratitude as well as modest pride—has steadily progressed in influence and recognition, and in the success consequent upon the possession of these. Notwithstanding the various phases through which photography has passed as a commercial enterprise, and the different aspects it has assumed as a science and an art, the PHOTOGRAPHIC NEWS has steadily acquired and accumulated friends, influence, and

popularity, and at no period were its friends, correspondents, and contributors more numerous or more active in its interests than they have been during the progress of the present Volume, as its contents bear witness. We make these remarks rather in grateful recognition of the valuable aid we have received from all quarters, than in any spirit of vain-glory ; we make them because silence in relation to the zealous interest of so many friends would be insensibility.

All these things proved long ago the need for such records of progress and such aids to progress as we have endeavoured to furnish ; and they prove that hitherto we have not entirely failed. For the future, this is not the place for entering at large into promises or pledges. We intend that whatever has been found worthy of recognition and approbation in our programme during the past shall be retained and amplified in the future. Our own work will be the same, only conducted with augmented experience. We aim to bring under the attention of our readers everything which can in any way, intimately or remotely, affect the interests of the art or its devotees ; but we also aim to aid their judgment in relation to all that requires consideration and examination before acceptance, that they may "prove all things, and hold fast that which is good." We are assisted in this work by a larger staff of regular and occasional contributors than we have before had the good fortune to possess, an augmentation of power of which our readers will continue to reap the advantage.

Thanking our numerous correspondents and contributors for the valuable aid which, during the past year, we have received in an unusual and unprecedented degree, we wish them, our readers, and the art, a very prosperous new year.

DECEMBER 31ST, 1868.

As a si knowledge. And if progress could only be  
keeping by the record of discoveries made, or novelties  
in comd, the past year might not unnaturally be regarded  
perim nignant and profitless one. Such an estimate would,  
or, be unjust, for notwithstanding the existence of  
that is depressing in the commercial condition of the  
ice, and much that is unsatisfactory in its practice, the  
Vital activity which has prevailed during the last twelve  
Months, the anxiety which has been manifested by many to  
levate the art, and to improve its results, are all illustrations  
of a healthy vitality in the photographic community, and  
indications of a promising future for the art.

There has been no change made in the ordinary negative  
process with wet collodion, although a better understanding  
of some of the conditions of success has been attained.  
An important aid to the preservation of plates during long  
exposures has been introduced by Mr. Valentine Blanchard.  
One of the chief difficulties arising during the long keeping  
of wet plates has arisen from the concentration of the free-  
silver solution on the plate, caused by evaporation. The  
concentrated solution has at times tended to crystallize  
on the plate and cause stains; at other times it has com-  
menced to redissolve the iodide of silver already formed in  
the film, and so cause stains. Mr. Blanchard has met the  
difficulty by employing a collodion with a larger share of  
bromide than usual, and allowing the plate to remain in the  
nitrate bath only a short time, so that a portion of the  
bromide in the film remains unconverted into bromide  
of silver. The result is that the free nitrate of silver solution  
left on the plate, instead of becoming stronger or more con-  
centrated by evaporation, is really becoming weaker by the  
process of double decomposition which is going on between  
the silver and the unconverted bromide left in the plate. A  
two hours' exposure in hot weather has produced no evil  
results where this method has been adopted.

Matt silver stains, pinholes, and streaks, have still con-  
tinued to trouble some photographers. As regards the first,  
besides the above means of prevention, the remedy we  
indicated a year or two ago is now generally recognized as  
meeting a large number of cases. We suggested the use of  
collodion which did not give a repellent film, the addition  
occasionally of a drop or two of water to each ounce of  
collodion, and the use of iodides with bases forming in  
the silver bath hygroscopic salts. With these conditions  
and usual precautions as to cleanliness of the inner frames,  
little risk of matt silver stains will be incurred. On the  
subject of pinholes, little or nothing has been added to our  
knowledge during the year; but known remedies meet the  
majority of cases. Streaks in the direction of the dip—a

simple trouble which has puzzled many experienced photo-  
graphers to get rid of—have made their annual autumnal  
appearance; but it is now generally found that the rapid  
vertical or lateral movement of the plate in the bath imme-  
diately on immersion, instead of allowing it to rest for half  
a minute as usual, completely removes the evil.

The importance of using a ripe collodion has excited some  
attention. With a freely bromized collodion, and one in  
which the iodide and bromide of cadmium is solely or  
largely employed, it is found that the collodion loses nothing  
in sensitiveness, and gains in many other good qualities by  
months or years of keeping. The experience of Mr. Eng-  
land, one of our ablest landscape photographers, verifies this  
practice.

In dry collodion processes the year has been more rich in  
good results than in any other branch of the art. Simpli-  
city, sensitiveness, and certainty have been attained in  
several processes in a higher degree than had before been  
secured in dry plates. A simplified collodio-albumen process,  
by Mr. England, in which the preparation of the plate is com-  
pleted at one operation and with one bath, has been found in  
his own practice sufficiently trustworthy to be employed com-  
mercially instead of the wet process; and during the summer  
he obtained by it upwards of 400 negatives of Rhine scenery.  
Mr. Bartholomew's acetate of morphine process is, perhaps,  
more simple and sensitive still, the exposure being less than  
double that of dry plates. Its only drawback is uncertain  
keeping qualities. Mr. R. Manners Gordon has worked out  
a modified gum process, which in keeping qualities and  
excellence of result leave nothing to be desired. A modifi-  
cation of Mr. Sayce's collodio-bromide process has been  
reduced to something like absolute certainty, and plates  
prepared by it and sold commercially at Liverpool appear  
to be, from many reports, uniformly excellent and trust-  
worthy. Little difficulty need now be experienced by dry-  
plate workers, since dry plates suited to almost any condition  
may be readily bought or easily prepared.

There has been but comparatively little progress in enlarg-  
ing processes. The most important novelty in this direction  
is the application of a well-known principle to a compa-  
ratively new purpose, by which very excellent enlargements  
are easily produced. An enlarged transparency is taken in  
the camera, toned to a suitable tint, and transferred to plain  
paper; the result, if well done, is a picture resembling  
an albuminized print. There are three definite advantages  
to recommend this method of enlarging: it is simple,  
and does not require either fresh apparatus or fresh ex-  
perience out of the usual range of a portraitist's practice;  
the delicacy of the image on collodion largely compensates  
for the loss of sharpness consequent upon enlargement; and  
there is considerable hope of permanency in a developed  
print on collodion, as it has, in fact, the same bases for  
stability as a negative.

In printing processes generally but little change has been made. Swan's carbon process has steadily progressed in commercial use, but has not been so generally adopted in this country as we hope to see it. In America and on the Continent it is coming into use, M. Braun, of Dornach, having hitherto adopted it most largely and successfully. Mr. Woodbury's process has not yet been commercially practised, but probably will be very shortly. There appears to be no inherent reason why it should not at once be generally adopted for many purposes. Involving, as it does, entirely new principles of printing, requiring new and costly plant, and newly trained workmen, it has laboured hitherto under commercial disadvantages which have delayed its application. Mr. Woodbury has been busy in working it out in various directions, and has during the year produced 10 by 8 pictures in all respects equal to silver prints.

Silver printing remains much as it has done for some years, its practice in skilled hands having attained a high state of perfection. Some slight attention has been given to methods of eliminating the last traces of hyposulphite from the print, but chemical modes of effecting this do not seem likely to come at any time into general practice. There is little doubt that a carefully produced silver print, fixed in plenty of strong, fresh, neutral hyposulphite solution, and then thoroughly washed, will be as permanent as an image formed of reduced silver can be; and that, kept under favourable conditions, it may have a long tenure of stability. The chief difficulty is, that however perfectly produced, the very nature of an image of finely divided silver renders it liable to change; and hence the importance and desirability of using a carbon process. Hence also the desirability of a method of protecting silver prints from the action of the atmosphere and the agencies of change which are present in it. Mr. Blanchard's method of coating the print at both sides with collodion seemed very hopeful; but some experiences during the year, which have been described in our pages, have somewhat dashed that hope. The matter still requires further testing, however; the process has too many elements of promise to be abandoned without very full trial. The method of using varnishes for the same purposes is less desirable for general use, because of the unsuitable glaze it gives the picture. The use of wax is gaining ground, as improving the appearance of the print, whilst it makes it less pervious to injury.

The use of sugar in the printing bath, specially brought under the attention of photographers in our pages by Mr. Bovey, promises to be of great value in permitting the keeping of paper without risk of discoloured prints, and also, under some circumstances, communicating increased sensitiveness and intensity. The use of a toning bath of sulphocyanide and gold has received some attention during the year, and, for certain purposes, has been found to possess good qualities. Our collodio-chloride process has come into more common use on the Continent, and M. Obernetter has prepared a stable sensitive paper by a modification of our process, the prints from which appear to be very excellent.

Photo-lithography and photo-engraving have not made much progress, especially in this country. The process of phototypic by MM. Tessie du Motay and Mareschal gives the most perfect results we have seen. The method of producing photo-engraved plates of reproductions has received some attention on the Continent, and we have seen very good results. This branch of photography, which ought to have many valuable applications, has received singularly little attention in this country.

Much interest has been excited during the year by the accounts of the photography at the International Exhibition in Paris, in which this country, from a variety of causes, presented a much worse appearance than the condition of photography in England justified. Whilst we excelled in landscape, it was clear, however, that we were behind some continental countries in the art excellence of our portraiture. The magnificent portraits by M. Salomon, of Paris, took the photographic world by surprise, and, by

their boldness and vig-

delicacy and perfect mo-

freshness in composition, } contributors more  
photographic excellence were } ing the progress  
dreamed of; and a new impulse  
less been given to photographic p } remarks rather  
of these pictures.

An exhibition of photographs headquarters, than  
cess beyond anticipation. It had i-  
rate the new session of the Photograp-  
to the zealous  
an exhibition meeting, photographers,  
in examples of recent progress in the,  
In the course of one evening, contribut-  
of such excellence were forthcoming  
desirable to prolong the exhibition for  
respects it was the best photographic ex-  
prove that  
been held in London, and exhibited a  
activity and state of progress and impro-  
place for  
photographers.

Professional photography has continued  
depression, but there are symptoms of improv-  
cabinet portrait, to which we endeavoured to gi-  
last year which should aid in establishing it, ha-  
and on the Continent become a great success  
country it is progressing towards success, but ha-  
yet attained that position. With increased ec-  
prosperity in the country at large, and with increa-  
and excellence amongst photographers, who should 'at  
a higher opinion of their art, of its possibilities, and  
worth of its results, revived commercial prosperity w-  
doubt not, prevail amongst portraitists. As a contempo-  
has well remarked, "The art cannot die; it must advan-  
and already there are signs of a revival." That revival m-  
not equal the prosperity which attended the card man-  
but it will bring success to those who deserve it.

Death has been busy amongst the ranks of vet-  
photographers during the year. M. Claudet, the c-  
professional photographer in London,—one who P  
laboured with love and earnestness for the promo-  
of the art for upwards of a quarter of a century,—is  
gone. Mr. J. F. Goddard, another of the oldest workers, is  
also dead. Mr. Mawson, a name long familiar in connection  
with the preparation of photographic chemicals, was lost to  
the art by an untimely death. The Duc de Luynes, a name  
long associated with the promotion of permanent printing,  
and the prizes he offered to stimulate the production of such  
a process, he also is gone. Mr. Malone, an early worker in  
conjunction with Mr. Fox Talbot, is also amongst the men  
that are gone. The melancholy thought presses itself on  
the mind that the time is coming on when the names of the  
pioneers of our art will pass out of the field of action into  
the domain of history.

Let us all strive to do some work for the art first, and let  
us work while it is called to-day. In conclusion, we greet  
readers, friends, and correspondents with wishes for a  
happier and more prosperous new year than that has been  
which has just closed.

#### THE MOIST MORPHINE PROCESS.

SOME further accounts of the moist acetate of morphine  
process for keeping plates a few hours are very promising,  
and the simplicity of this mode of preparing plates for long  
exposures, or to be carried a distance, without the delay in-  
volved in using dry plates, possesses many advantages. Mr.  
Burgess writes, a few days ago :—

"I took out with me a plate prepared by thorough wash-  
ing and dipping in one grain solution of morphine. I gave  
two minutes' exposure with Dallmeyer's stereo lucses, No. 4  
stop. I should have considered thirty seconds sufficient for  
an ordinary wet plate. Developed with iron and gelatine,  
the result was a well-exposed, perfectly clean negative, about  
the same colour and density as an ordinary negative. It

was an hour and a quarter from the time the plate was prepared till the development."

It will be seen that in this instance Mr. Burgess gave four times the exposure he judged necessary. This exceeds the time generally judged necessary for the dry morphiue plates; but we may remark that considerable latitude of exposure is permissible with most processes in which free nitrate of silver is not present, and Mr. Burgess, always aiming at extreme delicacy in his results, is not likely to risk any degree of under-exposure. Mr. Bartholomew sent us a day or two ago a further hint on the process as follows:—

"Egham, Dec. 29th, 1867.

"DEAR SIR,—I find that one-fourth part glycerine in the morphine solution perfectly effective to keep a plate moist, and in no way interfering with sensitiveness or development, although kept twenty-four hours after preparation. This is a valuable quality on an emergency in hot weather. The lovers of albumen should try the acetate morphine in place of nitrate silver in the albumen coating of the plates. Of course, ammonia must not be present, but, if anything, acetic acid, in the albumen.—I am, dear sir, yours faithfully,  
WM. BARTHOLOMEW."

As a simple method of preparing plates for a few hours' keeping is one of the wants of photography, we have pleasure in commending this use of acetate of morphine to our experimental readers.

#### THE LATE M. CLAUDET.

We closed our last volume with the record of the death of one whose name had long been familiar to photographers, and we have the melancholy task of ushering in a new volume with a similar chronicle. Antoine Jean Francois Claudet, F.R.S. and Chevalier of the Legion of Honour, died suddenly at his residence in Gloucester Road, on Friday last, in the 71st year of his age. He had been active and vigorous and well up the time of his death. A recent accident in getting off an omnibus had confined him to the house for a few days a short time ago; but he had recovered, and had himself assured us, recently, of his perfect vigour. About a week before his death he called upon us and left a message asking us to see him shortly, as he had an interesting novelty to bring under our attention. The day before Christmas Day he made various appointments, and planned various duties at the studio in Regent Street, for the Friday following, on which day he suddenly died.

The labours of a life so devoted to photography as that of M. Claudet demand a more extended notice than we can give now; but a brief note of the prominent events, chiefly within our own recollection, may be interesting here. Although, as is well known, a Frenchman by birth, M. Claudet had been upwards of thirty years in this country, about eight and twenty of which had been devoted to photography. At the time when the discoverer of the Daguerreotype process was liberally pensioned by the French Government, in order that the art might be as free to the world as the sunlight by which the results were produced, a patent was secured in this country, and M. Berry, the agent in the transaction, had this patent for sale. M. Claudet—then engaged in the glass trade, as the partner of Mr. Houghton, a partnership which has since continued—became the possessor of a part, which consisted in the right to use three cameras in practising the then undeveloped art, portraiture not having at that time been attempted. Mr. Beard soon afterwards bought the patent, or the remainder of it, and commenced, in 1840, the production of photographic portraits. About the same date, but a little later, M. Claudet commenced the practice of portraiture in the Adelaide Gallery, where his studio remained for many years. Mr. Beard, not being aware of the nature of the rights in the patent previously acquired by M. Claudet, was not prepared for those operations in portraiture, infringing what he conceived to be

his sole rights, and applied for an injunction to restrain M. Claudet from the practice of photography. The latter gentleman, however, made good his claim, and has continued the practice of portraiture to the present day.

Having once entered into photography, he devoted himself ardently to its improvement and development, and has been always one of the most zealous workers in its promotion and elevation in all respects, as science, art, and profession. During the first year or two of operations in portraiture, a single achromatic meniscus lens was used, the diameter being about one inch and the focus three inches, the size of the plate being that known as the sixth size, or  $3\frac{1}{4}$  by  $2\frac{3}{4}$  inches. For years it was the practice to place the sitter in the open air to secure the most uninterrupted light. Much has changed since then, at least in the appliances of the art, although a serious question may be raised as to whether improvement in results has kept pace with improvement in means and appliances.

The earliest of M. Claudet's contributions to the art was a mode of obtaining increased sensitiveness by using chloride of iodine, instead of iodine alone. The use of bromine, however, superseded the use of chlorine, and M. Claudet availed himself of it, using a mixture of bromine and iodine as his second coating on the silver plate. The paper on the use of chlorine in the Daguerreotype process was read before the Royal Society in 1841, and his communications to the scientific progress of the art since that time have been constant. Although it is to the Daguerreotype process his experiments have been mainly confined, he took up the Talbotype process at a very early period, and was one of the earliest in the production of photographic portraits on paper. With the Daguerreotype process he was especially enamoured, and was the last to discontinue the practice of Daguerreotype portraiture in London. We are not certain that he did not up to the present time occasionally practise this process.

Of his multitudinous labours we cannot speak in detail now. His name is associated with so many inventions that we cannot in a brief obituary notice recall all. His dynactinometer, his photophometer, his focimeter, his stereomicroscope, his experiments in connection with binocular vision, his system of unity of measure for focussing enlargements, his moving focus and focus equalizer, his system of photosculpture, and many other results of his experimental researches, are familiar to most of photographers.

His contributions to photographic literature were copious and interesting, the idiomatic excellence and elegance of his English being remarkable. Although the scientific aspects of the art claimed his first attention, he was ever the ready and eloquent champion of its art claims. In controversy he was able and acute, but free from bitterness or acerbity, all his communications being eminently courteous and conciliatory. For many years he was a member of the Council of the Photographic Society, and frequently contributed to the proceedings. He had attained high recognition of his many labours, and, in addition to many medals, was a Fellow of the Royal Society and a Chevalier of the Legion of Honour.

Although he had attained the age of three score years and ten, he was still active and energetic in his experimental researches into the science of the art, literally dying in harness.

#### Critical Notices.

VIVIEN AND GUINEVERE. By ALFRED TENNYSON, Poet Laureate. With Eighteen Photographic Illustrations, from Drawings by GUSTAVE DORE. (London: Edward Moxon and Co.)

The notion of Dore's illustrating Tennyson seems at first sight altogether incongruous. What, it is naturally asked, can the exuberant and bizarre genius of the great French

artist have in common with the essentially English idyllic poetry of Alfred Tennyson? In giving form and life to thoughts of the wits and humourists of his own country, in depicting the grotesque situations of Don Quixote, in becoming co-creator with Dante of some of the scenes of the Inferno, and even in giving pictorial embodiment to some of Milton's grandest imaginings, we can understand Dore's success. But the unexaggerated sweetness and simplicity of Tennyson's style, even in dealing with English legends of heroic deeds in a period in which history and fable are undistinguishable, are the last qualities which it might readily have been said were suited to the pencil of Gustave Dore. Yet there are few, we imagine, who have seen his illustrations to *Elaine*, who will not look with eagerness for those to *'Vivien and Guinevere,'* and regret that they must wait for twelve months before his illustrations of *Enid* will be issued. Few who have once seen it will readily forget the solemn grandness of that picture of "the dead steered by the dumb" which formed the frontispiece of the first volume of his illustrated Idylls.

On second thoughts, few, even of those disposed to deny Dore's fitness for illustrating Tennyson, will be disposed to deny that something more is needed in the illustrations to a great poem besides moderately well drawn but slavish renderings of the text. These add nothing to the work of the poet, but often rather cumber it, and render it commonplace. Worthy illustrations to a great poem should excite the imagination in the same manner, if not in the same degree, as the poet has done. It is of less importance that he should servilely depict what the poet has described, than that he should catch the spirit of his author, and clothe upon it after the fashion of his own genius. In the works of M. Dore this mode of dealing with illustrations must inevitably be the case; the individuality as well as the originality of his genius is perpetually manifested, and if he fails at times in embodying what Tennyson describes, he always produces a grand picture which is imbued with the spirit of the scene to be rendered.

In "*Vivien and Guinevere*" M. Dore has entered more fully into the spirit of Tennyson's poetry than he succeeded in doing in "*Elaine*," and we have some of the most exquisitely tender and beautiful scenes which he has ever drawn. The Dawn of Love in "*Guinevere*" is an admirable example of this. The scene depicted is that in which Lancelot and Guinevere ride together in Maytime towards Arthur's court,

"Under groves that looked a paradise  
Of blossom, over sheets of hyacinth,  
That seemed the heavens upbreking thro' the earth."

Nothing can exceed the sweetness of this springtime landscape, the fullness of colour, and the glad beauty of everything which surrounds the knight and the lady in the dawning time of that unfortunate love. In "*Vivien*" we have examples of the half-grotesque, half-weird grandeur of Dore's pencil in the scenes in the wood, between Merlin and the lissome Vivien. We might point to almost every picture as having its especial point of excellence well worthy of the attention of the art student for lessons in composition, as well as of the admiration of the general reader.

The especial claim of this edition upon the attention of our readers is the fact that M. Dore's drawings are here rendered by photography, instead of by means of wood engraving, in which form his drawings are most familiar to the public; or by steel engraving, as in another edition of this work issued by Messrs. Moxon and Co. The drawings of Dore essentially demand the truth of photography if it be desired to see him in the original, and not in translation. The broad washes in which they are executed, the free use made of body colour, give a character too often lost in any method of engraving. Mr. W. Jeffrey has done the fullest justice to the artist, his reproduction leaving little to desire. Even by means of photography it is easy to miss the spirit of a picture in reproducing it. Under-exposure or over-exposure, under-intensifying or over-intensifying, over-hardness or

lack of vigour in the negative, or lack of judgment in the printing, would alike tend to mar the result. In the reproductions before us the photographer has done full justice to the artist, and we have rarely seen a series of more uniform photographic excellence. The work is one of which poet and artist, photographer and publishers, may alike feel proud of a share.

#### THE LANDS OF THE BIBLE. A Series of Stereographic Pictures, by FRANK GOOD, 47, Minories.

Mr. FRANK GOOD has, during the last two or three years, been rapidly winning a position as one of our first landscape photographers, and the series of stereographs before us will go far to render that position unchallengeable. We have in most of these pictures something more than good photography, although that characterises the series throughout in a degree rarely attained in Eastern photographs. Especially noticeable throughout is the artistic feeling which pervades the treatment of every subject admitting of choice or discretion, such as the careful selection of point of view, the judicious lighting, and the degree of tenderness and delicacy, or vigour and brilliancy, imparted to each picture, as the nature of the subject may have rendered desirable. Here is Nazareth (No. 41 of the series): a distant view of a town or village is rarely a picturesque subject, however interesting its associations; but we have here a bold, effective foreground of upland and stone and bush, with well-placed figures; the town occupying the distance and middle distance, and an effective sky and clouds giving harmony to the whole. The Sea of Bethsaida (No. 46) is another charming picture, well composed and full of atmosphere, a calm beauty pervading, such as might fitly have been given by a painter as a poetic treatment of a scene associated with such sacred memories. Of Jerusalem we have many views, all fine, and some very full of meaning: in one we have Turkish tombs and Arab shepherds as the leading feature; in another, Latin monks; whilst in a third the fine Hebrew masonry of the Well of Wailing has survived the changes which time has effected on the fortunes of the once holy city. Of Sinai we have also several excellent views; one of the best of which gives a view of Mount Horeb, with three Eastern figures seated on some stones in the vast amphitheatre formed by the hills.

The judicious introduction of figures harmonizing with the spirit of the scene and aiding the effect of local colour is a distinguishing feature of Mr. Good's pictures. At times it is made valuable in increasing the effect of desolation and of space in a gigantic ruin; and at other times is effective in giving the effect of the modern life of an ancient city. Of the former effect we have a striking example in the two or three figures, looking like pigmies, in their comparative little-ness, in the remains of the vast amphitheatre of the Temple of Bacchus. Of the effect of modern Eastern life we have many instances, both in the town and desert: here is a crowded street scene in Cairo, and here are European travellers on dromedaries led by Arabs.

The presence of skies with fine clouds, and the feeling of space and atmosphere, is more apparent here than in the majority of Eastern pictures. Nothing that we have seen of its kind exceeds in this respect a General View of the Temple of Jupiter at Baalbek (No. 66). Standing alone amid the ruins of its broken columns, splendidly lighted, with an admirable sky, this is a subject of rare grandeur, a fine example of breadth of treatment, and altogether a charming picture. Scarcely less effective is a view of the Sphinx and Great Pyramid (No. 97), taken under a blazing Eastern sun and cloudless sky; yet still a perfectly harmonious picture, giving a satisfactory sense of the solitary grandeur of the head which has for so many centuries been

"Staring right on with calm eternal eyes."

The Caryatides at Athens (No 84) is a very fine example

of lighting, a slanting cast shadow, from the eutablature resting on the figures, playing an important pictorial part in slide. We might multiply examples of distinctive excellence, but our space forbids. We have said enough to point out the presence of fine artistic taste and definite design and understanding of the work which characterizes these pictures, and which we have pleasure in noting is a growing feature in photography, of a very hopeful character.

#### SUNSET ON THE SEA. Photographed by H. SAMPSON, Southport.

This is one of those rarely beautiful examples of nature's pictorial effect which only instantaneous photography can render. The sun is hid by a grand mass of cloud, the edges of which are fringed with light. Immediately underneath, and in the track of light which the sun's rays form on the dark face of the sea, is a small sailing-boat, the only object visible, except the sea and sky and sun-fringed cloud, all of which combine to form an exceedingly charming picture. The print is with much taste cut into a circular shape, mounted on india-tinting, and is altogether very effective.

#### A VIEW OF NEW YORK, from Hoboken. Photographed by J. C. BROWNE.

This is a charming photograph with which we have been favoured by one of our American readers as an illustration of the working qualities of Zentmayer's lens of  $5\frac{1}{2}$  inches focus, the picture being eight inches on the base-line, and the amount of angle included, therefore, upwards of  $70^\circ$ , the definition being satisfactory throughout. This is attained, however, by the use of a smaller stop than we think desirable for any purpose where a satisfactory effect of relief and distance is to be obtained, the aperture here having been one-fiftieth of the focal length of the lens. The value of small thin lenses is, however, illustrated by the fact that, notwithstanding the smallness of the aperture, the exposure in this instance was not more than forty-five seconds. As a picture and an example of photography this photograph is most charming. Notwithstanding the unpromising effect of a subject consisting of a distant view of a city, with a river and the two parallel lines formed by its banks for the middle distance, these are so broken up by taking advantage of some shipping, and even by the aid of such unpicturesque objects as telegraph poles, that a very fine composition is secured, the well-placed figure of a girl in the foreground very materially aiding the effect. The picture is full of space and atmosphere, and is altogether charming.

#### STEREOGRAPHS OF AMERICAN SCENERY. By PROFESSOR TOWLER, M.D.

Our friend, Professor Towler, with whose name and writings all photographers are familiar, favours us with some pleasant transcripts of the beauties with which America abounds. These chiefly consist of rock and cascade scenery in the neighbourhood of Seneca Lake, the scenes all selected with an artist's eye, and photographed by a master hand. Our friend kindly invites us to spend a few weeks photographing with him in camp next summer at the Niagara Falls, and gives us his address as a tent on the College Grounds near the Rapids! How we should enjoy the trip, and the company, and the occupation, if the rendezvous were not just a few miles too far distant to permit us to discharge our duties on the News at the same time!

#### ECHOES OF THE MONTH.

BY AN OLD PHOTOGRAPHER.

MEN THAT ARE GONE—THE STATUS OF PHOTOGRAPHERS—INDIA-RUBBER FOR MOUNTING—SIMPLE METHOD OF ENLARGEMENT—SOCIETIES.

ANOTHER year's requiem has been sung, a year of some depression and of many sad memories, the last of which is

the loss to photography of an old knight and a true, Antoine Claudet. He was a middle-aged man when photography was in its cradle, and has watched it grow into a giant spreading its arms over the civilized world, shedding the light of its countenance in every spot where human affections find a dwelling-place, in camp and cabin, palace and cottage. He had seen this growth, and gallantly aided it. Few men ever gave such a whole-hearted devotion to an art. He was ever studying the subtleties of its scientific phases; he was actively alive to anything affecting its artistic character, and one of the readiest and ablest of its champions when its art claims were brought into question. In the late diffusion of focus question we did not all agree with him as to the best means of securing a given end; but few could deny that he ably pointed out a very definite lack in the art character of most photographic portraits, and that by his earnestness and energy he secured an amount of attention for this phase of the subject which it sorely needed; and in the discussions which arose on the subject he showed how it was possible to conduct a scientific controversy with firmness and decision, and maintain at the same time the perfect courtesy of a gentleman. Peace to his memory, which will live in the history of the art.

Others, too, are gone, and the echoes still vibrate with the sad story. But enough: it shall not be repeated here.

A topic which has always interested the "Old Photographer" has been the subject of two papers, some correspondence, and much talk during the month: How can the status of photography or photographers be raised? it is asked. Perhaps a question might fairly follow, Is the status of the art or its adherents lower than it deserves to be? What is the status of the art? It is practised by every class in the kingdom: royal fingers are occasionally found engaged in it; noble gentlemen and ladies are found amongst its amateurs; it is practised with zeal in what are termed the learned professions, the church, the bar, and medicine; and in the army and navy it is a favourite accomplishment. No art, in fact, can boast a wider popularity by amateur practice amongst all classes of the community, the most noble as well as the most plebeian. The status of the art itself, then, cannot well be complained of. It is true its position as a fine art is not as thoroughly recognised as some of us could wish; but that is not quite unnatural. In the first place, the art is young, and elder sisters are proverbially slow to admit to terms of equality the young chits of girls. Photography must undergo her period of probation, and make good her claims, before she can be unhesitatingly admitted into the sisterhood of the arts. The more guarded a circle, the more a position within it will be valued; and it must be admitted that much that has been perpetrated by photography has not been of a character to qualify her for a position in the sacred circle. Still, in the status of photography itself there is little to complain of.

But it is the status of professional photographers which is to be raised, and this, I must confess, is a far more difficult question. But again, I would ask, is the status of professional photographers lower than they merit? I shall be the last person to ask this question offensively. I shall be the first to commend any effort to raise their status and to increase their prosperity. But it is as well to be honest in dealing with such a question. Is the social position and recognition of photographers as a body lower than their education and character entitle them to occupy, or than they would have occupied if they had been engaged in some other mode, possible to them, of making an income? And, further, is the income derived from the professional practice of photography less than would have been made by the same persons by other modes of making an income possible to them? I do not attempt to dogmatize, but I think that both these questions must be answered unhesitatingly in the negative. Further, I think that, in many instances, photography has been the means whereby many have acquired much larger incomes, and have risen to a much higher status, than they would otherwise have secured. Doubtless they were the men

who possessed naturally the element for rising. But to rise two conditions are necessary: the ability and the opportunity. The men who have risen possessed the ability, and photography afforded the opportunity; and to photography many of them have much reason to be grateful as a means of better income and higher status than they might otherwise readily have acquired.

That photography, as a profession, should have a high conventional status is scarcely possible. The bases of conventional status in professions are qualification and limitation or exclusiveness. In the learned professions only the limited number can enter, who by means and education can acquire the qualification and the prescriptive rights appertaining thereto. To belong, then, to these professions not only confers status, but is *prima facie* evidence of possessing fitness for it. In the practice of the liberal arts an aspirant has to make his own status, win his own spurs; and a painter or a sculptor who, either in virtue of great genius or careful education and earnest culture, cannot produce works of art, will not only never acquire any status in these professions, but can scarcely acquire a recognized position in their ranks. But how is it in photography? How are the qualifications for practising it obtained? Whence come the men who practise it professionally? The very fact that they spring from all conditions in life is one circumstance which must deprive the profession as such of any especial status. The men who, educated for other positions, have adopted photography and succeeded, who have won their spurs by natural aptitude and careful culture, do acquire status, and have no need to complain. Men of less skill and culture, however, clothed with privilege or dignified by diploma, could not command status or recognition if they produced inferior work. In short, the argument resolves itself into a nutshell: every photographer can make his own status. If his work be good and his mind cultivated, he will secure both profit and position. Public recognition alone can confer status, and good work alone can secure public recognition; and in proportion to the number of skilled artists and cultivated gentlemen in the profession, so will the general status and recognition of the profession stand in the public mind. To secure the desired improvement in this respect the process of natural selection, referred to in your pages last week, must take place. I agree with the writer, who remarked, that "the strongest will excel, and excellence will succeed, and the weakest will go to the wall."

I have noted with some interest a slight tendency amongst some photographers to revive, or rather to introduce as a novelty, the use of india-rubber for mounting prints. It is really one of the oldest materials which have been used for the purpose. I have used it a longer time ago than I care to say. For mounting prints in albums, and avoiding cockling, it is of undoubted value; but I fear that much disappointment will be experienced if it be much used for ordinary mounting purposes, as many of the prints will, unless I am mistaken, leave the card. The adhesion cannot be so perfect as that secured by paste or glue. I imagine, however, that the cost will effectually check its general adoption. If the claims made for it—of adding to the permanency of the print—be verified, I shall be glad, however, to see it again tested.

I have been much pleased with a sight of some enlargements produced by the simple method recently described in these pages. Is it not surprising that a method so easy and so obvious should have so long remained neglected? Any photographer who has or can contrive a camera extending two or three feet may produce such pictures with little trouble; and, if managed with skill, the effect is really beautiful. The question of toning seems to present some difficulties, as most of the specimens I have seen are too cold; but that is a difficulty which will doubtless be overcome if the method come into practice as much as it deserves.

At the Photographic Societies the most important topic

has been the status of photographers, to which I have already adverted, and which has been discussed at two meetings,—those of the Parent Society and the South London. At the latter an interesting paper on clouds was read by Mr. Howard, illustrated with some capital examples. I take it that when a photographer can conveniently secure clouds in his landscape negative he assuredly will do so; but as there are many occasions on which good pictures can be obtained in which there are no clouds in the sky at all, and many occasions when none that are in the sky come within range of the lens, few photographers, caring for pictorial excellence, will neglect the valuable aid to harmonious composition which double printing offers them, and the advantages of which Mr. Howard so well illustrated. At the North London Mr. King again introduced architectural photography,—a hobby which he likes to ride, and which he rides well. His advice to photographers to study a little of architecture to enable them to photograph with judgment and select the objects and parts of things worth rendering, is worthy of hearty endorsement; the more so that most men who commence to study architectural art with an ulterior purpose will continue it for its own sake, finding in it its own exceeding great reward, as opening out pleasures and the perception of beauties of which the uninstructed little dream. At the Manchester Society Mr. Winstanley read a good paper on enlargements. In the course of the evening the subject of india-rubber mounting was discussed, and from some of the examples exhibited my opinion of the imperfect adhesiveness appears to have been confirmed. At the Edinburgh Society a capital address was delivered by the President, who rightly enunciated the Horatian maxim, that as neither gods nor men can tolerate mediocrity in poetry, it ought not to be tolerated in photography. Mr. Slight also read an excellent paper on Societies. The South London Society held its annual dinner, which was a pleasant social meeting, and the community which exists amongst the arts was illustrated by many of the members giving tastes of their high quality as musicians, and some as humourists and lyrists, three original photographic comic songs having been sung on the occasion.

In conclusion, the "Old Photographer" wishes to the numerous friends and readers of these pages the happiest of happy new years and all prosperity.

### Foreign Miscellanea.

At the last meeting of the Paris Photographic Society, held on the 6th December, M. Despaquis invited the inspection of the members to some specimens of carbon printing upon sheets of mica. Although the material used was by no means of the finest quality, the prints, when viewed as transparencies, presented no apparent defects to the eye, but were of surprising fineness and delicacy.

At the same meeting M. Davanne exhibited, in the name of M. Manillier, a very simple piece of apparatus designed for the purpose of facilitating the mounting of photographs. It is composed of two sheets of cardboard put together in the form of the cover of a book. The inner surface of one of these boards is covered with white varnished paper, on which are traced horizontal and vertical lines dividing the surface into a large number of squares of equal dimensions. The two lines crossing the middle of the card in the direction of length and breadth are numbered from the centre, where they bisect one another at right angles, the numbers being repeated on each side. A print which has been coated with mounting material is placed face downwards on this species of draught-board in such a manner that the centre of the picture exactly covers the middle of the cardboard (where the two central lines cross one another); this is easily done by placing the extreme corners of the print upon such squares as bear similar numbers. The mount is then fitted over the squares in the same manner, the margin being allowed for and calculated from the number covered by the print; the two boards are then pressed firmly together, and the picture is mounted in a very prompt and accurate manner.

M. l'Abbe Laborde read a paper on the causes which, beyond the action of light, tend to alter the blacks and whites of photographic prints. He attributed a great deal of the alteration to the deposition upon the print of a small quantity of mobile silver, which during the treatment of the print in the different operations is moved from one portion of the picture to another. To remedy this inconvenience M. l'Abbe Laborde recommends the employment of a bath, after the prints have been fixed, composed in the following manner, viz. :—

Bichromate of potash	...	...	3 grammes
Perchloride of iron	...	...	1 gramme
Water	...	...	150 grammes

In the *Moniteur de la Photographie*, M. Leon Moock reports progress with regard to the formation of an association of operators and others connected with the art of photography in Paris. By combining together, M. Moock is in hopes that the position of photographic *employés* will be notably improved, both from a moral and pecuniary point of view; he asks for immediate and energetic co-operation, both on the part of masters and assistants.

*La Science pour tous* makes the following statement with regard to foggy baths:—"Sometimes when the plate is removed from the bath it is found to have become fogged, and when the image is developed the latter is found to be quite useless. M. Torry, who has carefully studied the question, asserts that fogging is never met with excepting in baths containing impurities, and that it is an error to suppose that old baths are the cause of fogging, for experience has shown that baths of this description always furnish clear negatives. Old baths lose their sensitiveness, but have no disposition to fog.

"The real causes of this inconvenience are: firstly, the presence in the bath of small quantities of developing agents derived from the hands of the operator when coating a plate previously to its immersion in the silver bath; and, secondly, the employment of alkaline collodion. It is well to prepare one's own collodion, as all collodions of commerce are of an alkaline nature, and are incapable of furnishing negatives of a very transparent character. To prevent the apparition of fog in negatives, it is merely necessary, therefore, after having prepared a bath of the greatest purity, and renounced the use of alkaline collodion, to see that the hands are perfectly clean during the operation of coating the plate, and to take care that the bath is always properly covered, so as to ensure its preservation from any impurity.

A correspondent of the *Moniteur* extols the beauty of the glazed leptographic paper, but recommends the coating of prints prepared from the same with a preservative solution after they have been toned and fixed, as during the operation of mounting the prints are not unlikely to be injured. When, therefore, the prints have been washed and dried, they are coated with albumen (half water and half white of egg) by means of a tuft of wool dipped into the mixture and drawn slowly over the surface to prevent the formation of froth and air-bubbles. After drying, the surface cannot be injured by friction, and the pictures gain considerably in brilliancy.

M. Thomas writes in the *Archiv* that he has been making a careful trial of Professor Towler's nitro-gelatine developer, but has been unable to obtain successful results. He believes that probably Prof. Towler has used a description of gelatine which he is unable to obtain, or possibly there may have been an error in the formula.

The *Photographische Correspondenz* contains an exhaustive article, by M. Alois Nigg, on the best method of building photographic studios. M. Nigg goes fully into all details, and explains his ideas by means of well-drawn diagrams.

The *Archiv* recommends the lacquering of all zinc vessels used in photographic operations, as pictures manipulated therein are apt to contract yellow stains when allowed to remain in contact with the metallic surface.

In the *Mittheilungen*, M. Weber communicates a formula for obtaining a good negative varnish. It is as follows:—

Best yellow shellac	...	...	1 lb.
Alcohol	...	...	2 lbs.
Ordinary resin	...	...	z
Venetian turpentine	...	...	1 oz.

The shellac does not dissolve entirely, and the thick, turbid solution is filtered through coarse blotting-paper, a little more alcohol being added if necessary. To clarify it, the mixture must be allowed to stand for some time. It is poured over the

plate in the usual manner, the latter being slightly warmed previous to the operation.

M. Weber likewise makes known (in the same journal) a very simple means of copying and enlarging cartes-de-visite and other small photographs. By the employment of a very simple piece of apparatus he is able to prevent—at any rate to a very great extent—the mealiness and granular character generally presented by a copied or enlarged photograph. The apparatus he uses is a kind of box—or, more strictly speaking, a tray or trough of cardboard—the four sides of which slope inwards towards the bottom at an angle of 135°, and are covered with tin-foil; the picture to be copied is fixed at the bottom of the apparatus, and the whole hung up in the front of the lens. A photograph is then taken in the ordinary manner, when it will be found that the reflection obtained by means of the tin-foil from all sides will have the effect of securing a picture almost perfectly free from grain.

At a recent meeting of the Berlin Photographie Society, M. Linde, of Gotha, exhibited a camera constructed to open and close by mechanical means, so that the period of exposure might be regulated with the greatest nicety and precision. When the time of exposure has been fixed upon, a hand is moved to the desired figure on the second dial, the camera is opened, and the clockwork set in motion; the apparatus then closes of itself at the prescribed moment. The apparatus, which can be used with lenses of different sizes, can be constructed for £3.

## FIRESIDE MUSINGS.

BY W. T. BOVEY.

No. 3.

### EDUCATION AND QUACKERY.

NEXT to Fenianism, the question of education has become the sensational topic of the day, and the way to set about the serious task of reformation is a problematical nut that the teeth of no statesman have as yet succeeded in cracking; although, judging from the startling predictions that seem to be borne on the wings of every passing blast, the position is critical, and the quicker the kernel is withdrawn from its hiding-place the sooner will the fears of trembling Albion be dispersed. Why did that fussy French Exhibition so ruthlessly tear asunder the veil that concealed from the eye of egotism the near approach of the "tortoise"? Why has it so unceremoniously dispatched the grey-bearded notion that education for the masses were broad-swords, barricades, and revolution concealed in sheep's-clothing? Above all, why have our Continental neighbours so conclusively shown that popular instruction yields new vigour to skill, strengthens the arm of state, and extends, whilst improving, the several fields of human industry? To those who have enjoyed the advantages of superior tuition it doubtless appears a mystery that England's boast, a cheap press, which, with untiring energy, continues to send forth daily newspapers, weekly journals, and monthly periodicals by tens of thousands; that creates mountains of volumes on every conceivable subject, and consumes as much paper annually as would carpet a continent, should, in spite of its Herculean efforts, have failed in making headway against the stream of ignorance. But to the laborious few whose secret yet resistless impulses have enabled some of the formidable difficulties that accompany efforts at self-culture to be surmounted, the problem is one that admits of ready solution. For, startling as the statement may to some appear, the greatest clog on the mental labours of those "who consume the midnight oil" is a lack of teachers. True, of a certain class, they have preceptors whose name is legion, but how few among them who are qualified to occupy the important positions they assume! How limited the number who strive more to smooth the path of knowledge than to create "mountains out of mole hills," that their own superiority, magnified, might hurl a shaft of timid awe into the breast of the plodding student! Ho! for teachers whose hearts are large enough to hold the spirit of philanthropy, whose armour of modesty and common sense is sufficiently stout to enable its wearers to do battle with those hydra-headed monsters, pre-

tention and ignorance; and who are honestly bent on adopting as their motto and guide, *No quackery; genuine instruction. Not self-buffing and self-glorification.* We want teachers who can make straight the barbarous and crooked jargon that mystify the laws we are, under pains and penalties (held in *terrorum*), bound to obey. Teachers who can set their backs against a nauseating nomenclature, and impart to the outside world a clearer knowledge of that wondrously wrought creature man; and sounder information concerning the pills, potions, and bitter draughts administered to him in his hour of suffering. Teachers who trample under foot the veil of quackery that conceals from the million their Maker reflected in every flower, His power displayed in every blade of grass. Teachers who, in the words of Sir John Herschell, can boldly declare "that everything which, to keep up an appearance of superiority in its professors over the rest of mankind, assumes an unnecessary guise of profundity and obscurity, should be sacrificed without mercy." Teachers who are not afraid to attack the stronghold of scientific humbug by scattering to the winds those ponderous, long-winded words and mystified sentences that mean just nothing; and so lay bare the truth in all its nakedness, that knowledge, at its best, is very ignorant indeed. Teachers who are not for ever thrusting their pupils over the fathomless precipices of metaphysics and false logic. Finally, as a turning-point to our musings, we ask teachers of art principles, for the sake of British photographers who, lacking such knowledge, have sunk into a slough of despond; for have they not been teachers of their foreign brethren? The public press has driven the nail of conviction, and "a Loudon Photographer" has elenched it home.

Reader, have you not of late felt more than usually inclined to deep thought when sitting at your own fire-side? And have you not poked the fire in wrath as the significant sentence recurred to your mind, "English photographers must kneel" before the superior skill of the foreigner? Of course you have, and your proud English blood has tingled in each vein as you scratched at your locks to give some degree of vent to your vexation. Friend, cease to wonder; the reason why of your discomfiture can be briefly told. You are without art-knowledge, and are afraid to seek it. You have been so lectured at, and scolded at, by quack teachers, that in your innocence you have been led to regard art principles as something akin to alchemy and art-teaching. You can scarcely believe them mortal; nay, in your more nervous moments you are wont to fancy that artists are spiritual essences who breakfast off rosebuds and sup on moon-leaves. Pshaw! whisper! We have seen artists nursing cross babies, and have increased the family consumption by joining the artist papas to a bout of beer and bread and cheese.

If this true statement does not bring your ideas earthwards your case is hopeless indeed. Seriously, you are deficient in art-knowledge, and require teachers, not charlatans. Apart from the occasional crumbs extracted by the over-taxed editors of your journals from an ocean of froth, the lessons on art subjects you have received have in most instances proved indigestible and fruitless. Such frizzings about feelings, the philosophy of æsthetics and arts grandeur! Such whizzings of glowings and raptures! Such stringings of sparkling poetry and metaphysical profundities, and such a bang! bang! bang! of learned quotations to show the amplitude of the teacher's marvellous range of erudition.

The Exhibition, taken as a whole, may be likened unto an effort of pyrotechny that dazzles for awhile, but the last thunder that dismisses the climax makes night more black, and darkness more intolerable. "Poetry"! "feeling"! "mystery"! Fiddlededee; time enough for raptures when the student can finger his instrument. Example: Music and painting are twin sisters. The first seeks sympathy through the medium of the ear; the second, from that swift messenger, the eye, chief guardian of the brain; and both awake sensa-

tions generally recognized as emotions or feelings. Admitted! Well, place a flute into the unpractised hands of a novice (one who scarcely knows which end of the instrument is intended to be blown into), and, in the most eloquent and flowery language you have at command, bid him produce music that will draw angels down to listen. Describe to him the glories concentrated in sound, and request that he will endeavour to imitate the heaven-born harmonies of Handel. Speak to him of the wondrous "Messiah," the wonderful "Creation," the sublime thunders of the great Hallelujah Chorus, and when you have puzzled your pupil, and glorified yourself to your heart's content, place before his bewildered gaze the music of some grand oratorio, and bid him play on.

"Squeak—pshew—foo-foo-foo-oo-ooo-o." "Pearls thrown to a certain animal." You would perhaps feel disposed to exclaim, Stop! The two the pupil is the most rational. He did what he could, modestly, and failed. The preceptor, in his anxiety to polish his own person, lost sight of the fact that, in addressing his sublimities to a learner he succeeded only in making himself ridiculous. The pupil needed teachings that would lead him by gently progressive steps from the A B C of notation, through the difficulties attached to "time," up to a complete acquaintance with his instrument, and the grand science of harmony, leaving feelings to develop themselves at their own good time and pleasure. Sound tuition might impart a perfect knowledge of mechanical music, but all the preachings and teachings of the universe could not create an emotion in a torpid soul. Feelings are inborn, and are but echoes to sensations that vibrate within the more mysterious recesses of the brain. They are the spiritual telegraph wires that connect mortals with heaven. As with music, so with art; the student must climb progressively, beginning at its A B C, and following the track until he obtains a perfect knowledge of principles, and confidence in submitting them to practical duties; then, if there is any feeling in him, it must out. Photographers are far in advance of our model flute blower. They can do something better than a "squeak;" but in too many instances we are wont to produce "discord" through having to play by "rote." Our ears require training, and we need a skilful hand to guide our studies. Our impression is, that progressive lessons would prove effectual; and we feel convinced that art knowledge bereft of its mystic mantle of jargon would assume a very attractive shape indeed. So much so, that the time would be nigh at hand when it would no longer with justice be said, English photographers must kneel before the superiority of foreign skill. Oh, then, for a large hearted art teacher! N.B.—No quack professor need apply.

#### PRICES OF PHOTOGRAPHS IN AMERICA.

AMONGST our trans-Atlantic brethren, as in this country, a feeling has long been prevailing that over-competition and low prices are tending to destroy portraiture as a profession. In New Orleans a meeting of photographers has been held, at which a step in imitation of trades-unionism has been attempted. According to our esteemed Philadelphia contemporary, it was unanimously agreed to advance the prices of photographs, as it had been ascertained that at the low rate we have been charging it is impossible to give good work and live thereby. The resolution on the subject runs as follows:—Therefore, it is mutually agreed that we will, from and after November 1, 1867, charge the following rates as per schedule below, binding ourselves not to deviate from the same under the penalty of being dishonoured and forfeiting the confidence and esteem of the fraternity. In future our aim shall be to excel and advance our beautiful art, instead of, as heretofore, cutting down prices and giving poor work. All lovers of the fine arts will sustain us, and we ask the public generally to encourage us in our laudable efforts:

*Schedule of Prices for First-class Galleries.*

Cards, original, per dozen .	\$5 00
" " " half dozen .	4 00
" duplicate, per dozen .	4 00
" " " half dozen .	3 00
Whole-plate, original, each .	5 00

" " duplicate, each .	4 00

*Schedule of Prices for Second-class Galleries.*

Cards, original, per dozen .	\$4 00
" " " half dozen .	3 00
" duplicate, per dozen .	3 00
" " " half dozen .	2 50
Whole-plate, original, each .	4 00
" duplicate, each .	1 50
11 x 14 plate, original, each .	9 00
" " duplicate, each .	3 00

Signed by all New Orleans photographers.

The dollar is, as our readers know, equal to four shillings and sixpence; we do not enter into the question of the rate of exchange or the relative value of gold and greenbacks. A correspondent of the same Journal remarks:—"I believe there are many who grumble at low prices, who have no right to work a camera at all, and who would do better to first take your Journal and study it and the examples in it, and make their work *worthy* of a good price before they complain. It is my experience that the better work I do the more I can ask for it. If my fellow artists will strive to improve their work, good prices will surely follow, and only those who do badly will have cause to complain."

## THE MAGIC LANTERN AND PHOTOGRAPHY.

BY JAMES MARTIN.

## No. 3.

HOLDERS may contain a series of circles, the number being according to their length. Take a piece of wood, planed up, of the length, breadth, and thickness required; make a pencil line right along its centre; on this line mark off a space of half an inch from one end, then the width required for the diameter of the picture, then another space of half an inch, and repeat until the proposed number of circles and spaces are registered, taking care to have an half-inch space at each end. Having set your circular gauge to the semi-diameter of the circle required, thrust the bradawl point into the long line at the proper place, mark out the circles, cut out the spaces with the keyhole saw, then, having marked off two pieces of veneer on the same plan, proceed to finish the back and front, making the same allowance for the rebate as for a single circle. Oval openings would look well for portraits, and be a novelty. The picture need not be cut to that shape, as the receptacle behind may be square. There is one more holder that is easily made; it is merely an oblong frame, having a groove round its inside face to receive the picture. The groove may be formed by a wide saw cut, or by cutting its sides with a cutting gauge and then taking out the centre strip by a small chisel; this is best done in one long piece before attempting to put the frame together; one side of the groove must be thin, that the picture may be placed as near as possible to the condenser. The proportions of the frame are governed by the size of the lantern and the picture to be fixed in it; its principle is like that of a boy's slate frame, and the corners may be put together after that plan. There are also the double-action, rotating holder for chromatropes, the single-action ditto for showing smoke, moving clouds, mill sails, &c., with brass rack-and-pinion action, but can be made of wood on the principle of cord and pulley. To make these would require a skilled mechanic, well versed in the use of the lathe, and hard and well-seasoned wood. Lastly, there is the lever slide holder, with rim and handle of brass.

Now supposing that the transparencies have been made of proper size, clear, bright, and without blemish, and the holders ready to receive them, we will proceed to prepare to colour them. For this purpose I will describe the proper instruments and colours, and how to use them. The glass easel, as being the *sine qua non*, I will speak of first. To make it, hinge together two frames about fourteen inches square, one inch and a half wide, and half an inch thick; now consider its hinged side the bottom side. Hinge also two supports same width and thickness as the frame, six inches long, one to each of the two sides of one frame on its face, so that when it is raised at the end opposite the hinges the supports will rest upon the lower one; cut a rack in that, to prevent the supports slipping, place a piece of glass of sufficient size to cover the frame before it, and the easel is made.

It is, however, as well to add a movable bar in its front, for the purpose of raising or lowering the glass as required; therefore bore a row of holes along the centre of the two side fronts of the frame to be raised by the supports, opposite each other, make a slight bar of wood of sufficient length to reach across the frame, having a hole at each end so bored as to come opposite to the poles on each side the frame; now, having two brass pins, place the bar across the frame at such a height as may be convenient, thrust them through the holes of the bar and into corresponding holes in the sides of the frame, and fix the bar tightly on; rest your plate of glass in it, and against the frame, having first raised it to a convenient angle for painting upon. The next requisites are a glass slab and muller (its face to be unground); a sheet of white paper; a clean rag; a few small, clean, dry glass bottles with corks; some camel-hair or sable pencils of various sizes, fixed on sticks; a small T square (which will be more useful provided it has a bevel, working on the crosspiece by a screw in a collar); a pen-knife having a lancet-shaped point; a small palette-knife; a few pieces of glass one-sixth size; a small straightedge, to rule lines by; a mahl stick (which is only a light stick or cane of sufficient strength to rest the arm upon, to steady the hand whilst painting); also a dabber or two, made thus,—cut out a piece of an old kid glove where there are no stitches, put sufficient cotton-wool into to make it look (when tied up) like a ball, about as big as a boy's marble, having a little handle, or perhaps more like an artist's bladder of oil colour; a paper stump, a few common sewing needles of various sizes, fixed in small handles—broken ones will do—using the pointed ends to work with on your painting. If circles are to be painted, an oblong holder should be made of mahogany about one-eighth of an inch thick by an inch and a quarter wide; its extreme length may be seven inches and a half and five inches and a quarter in width; its outer angles must be truly square; the inside measure will be five inches by two inches and three-quarters. Now cut away the sides of the inside space equally, so that they may form a diagonal one of four inches by two inches and three-quarters, the bottom and top remaining uncut. Supposing it finished, place it flat on the table, place a circle in the larger end, push it smartly towards the lesser end; now raise up the whole together, and you will find that it can be handled in any way without danger of the circle falling out. With the T square placed on its outer edge, as required, upright or horizontal lines can be drawn with the greatest truth at any part of the circle; and with a bevel, diagonal lines also. The size of the holder as now given is intended for circles about three inches and a half diameter; for larger or smaller ones, the inside dimensions must be altered accordingly.

114, High Street, Ilfracombe, North Devon.

ERRATA IN No. 2.—For "muller and tone" read "muller on his paintstone," line 22, paragraph 3; for "screw" read "screen," line 7 from top, right hand column; for "three-fifths" read "three-eighths," line 12, 2nd paragraph, right hand column; for "keyhole-frame saw" read "keyhole or frame saw," line 32, 2nd paragraph, right hand column; the word "under" misplaced, read "and only

under," line 5, page 608. In a few copies of the News a printer's accident misplaced some letters, which will not lead the reader into error.

### STEREOSCOPIC MICRO-PHOTOGRAPHY.

THE QUEKETT MICROSCOPICAL CLUB, the successful progress of which we have recorded from time to time, has just issued the first number of a Quarterly Journal of its proceedings, under the editorship of Mr. Hislop. Amongst other interesting papers we find some good remarks on microscopic photography, and on the illusionary effect of relief, at times produced in viewing flat surfaces in the stereoscope. The writer remarks:—

"Every one who has dabbled in photography, and at the same time possesses a microscope, must at some time or other have been impressed with the extreme suitability of the process for producing precisely what was wanted in the delineation of minute objects. Pictures can be produced by this process so extremely minute in detail as absolutely to require a hard surface and the use of a magnifying power to bring them out properly. Many have experimented in this direction, but foremost amongst them all must be reckoned Dr. Maddox, whose exquisite photographs of microscopic objects have far surpassed anything that has been published in Europe. Dr. Maddox favoured us with a visit at one of our recent meetings, and exhibited there some of his latest productions, which were most admirable, both in pictorial effect and faithful representation. Some of these pictures were of the markings on diatoms, such as *Pleurosigma Formosum* and *P. Angulatum* magnified 3,000 diameters, and were exhibited as tending to solve the question as to whether they are in relief or not. For this purpose Dr. Maddox views them stereoscopically, when most certainly this effect of relief is produced. Some stereo-photographs of *Pleurosigma Formosum* exhibited by him, when placed under the stereoscope, showed the dots as hemispheres standing in closer proximity to the eye than the surface of the frustule upon which they appeared to be set; in fact, presenting the appearance of so many minute ivory balls. Attention was also drawn to the fact that some of the diatomaceous discs, when viewed stereoscopically, are seen to be composed of two surfaces, an outer and an inner one, with a certain amount of structure between them. Mr. Bockett drew attention to an experiment of Mr. Beck's, in which that gentleman photographed a portion of a glass tumbler, on which the pattern was produced by hemispherical protuberances 'like so many plano-convex lenses on a convex surface,' in which photographs there was a tendency to exhibit those hemispheres as hexagons, according as their tops or bases were focussed by the lens.

"We very much fear, however, that the stereoscopic test is hardly reliable. Very considerable apparent modifications of form are produced by varying the condition of binocular vision. Apart from the fact that if you change the pictures from one side to the other you will find the relief become depression, and *vice versa*, it will be observed that if a perfectly flat picture be examined by a pair of short focussed stereoscopic lenses, it will appear to stand up precisely like the field of a binocular microscope. Take a negative of a black disc, for instance, and print two copies of it either on glass or paper, place the two side by side in a stereoscope, and, although pictures of a flat surface, the effect will be that of a convex one.

"Apart from these considerations altogether, there can be no doubt that Dr. Maddox deserves well of the scientific world for his arduous labours in delineating minute forms. Many of his beautiful productions may yet be seen at Mr. How's, Foster Lane, Cheapside, although we very much regret to say that, considered commercially, they have not met with the success which they merit. More than this, after seven years' labour in one direction, this zealous worker finds his sight is injured, and, for want of the successful publication of his works, is compelled to give up the further

pursuit of his experiments, without having realised that pecuniary reward which his unwearied efforts so eminently deserve."

### LECTURES ON ART.

THE Cantor lectures on art recently delivered before the Society of Arts by Mr. R. Westmacott, R.A., F.R.S., although referring especially to sculpture, contain much of interest and instruction for all art students. We append an abstract of some portions, condensed from the Journal of the Society.

In the first lecture, after expressing the pleasure it afforded him to accept the invitation of the Council, and some comments on the want of general education in art, he remarked that the fallacy of the opinion that any one unacquainted with the true principles of art can be a competent judge of works of art was gradually gaining ground. It was admitted that to judge of the merits and value of any of the ordinary products of industry required some education in the particular branch of science or skill to which the object belonged; but in the matter of art every one thought himself capable of forming a correct judgment. It appeared to be the opinion of some that if a picture or statue afforded pleasure to or satisfied its admirer, and possessed qualities that hit his peculiar liking or fancy, such a work was to him a work of beauty and merit. There could not be a greater mistake. It was a distinct question. It was one of liking, not of merit or beauty. A vulgar, commonplace work of art could not be other than vulgar, however and by whomsoever it might be admired or preferred. But knowledge added to enjoyment. For instance, a musical work might be performed in a mixed company, and nearly all would listen to it with a certain amount of pleasure; but how much greater would be the gratification, and how much higher the enjoyment, to educated musicians, who could not only listen to the melody, but enter into the train of thought, and appreciate the power of combination, evidenced by the composer, in producing a work of character, expression, and beauty. If this were true of music it must be equally true of painting or sculpture; for what words and rhythm were to the poet, and sounds to the musician, colour and lines were to the painter, and form to the sculptor. To attain to anything like a just appreciation of art required education; and none but true artists (he meant those who really understood the true principles of art), whether professional or amateur, could be considered as trustworthy judges and guides in matters of art; for it was not sufficient that the object should afford pleasure to constitute it beautiful or worthy. This was illustrated by the affection of a mother for her child, which was utterly irrespective of its beauty. No one could look around him and see the multitude of miserable little objects, which were so naturally the objects of affection to their parents, and say that, because they were loved (or, as in art, liked and admired), the poor, afflicted children were therefore beautiful. It was not only the deficiency of art education in this country, but the want of efficient encouragement for the production of high and noble works of art, that was to be regretted. Artists in England did not seem to aspire to anything heroic and noble in their works, as did those of Greece and the great artists of Italy in times past, but they appeared rather to work down to the present low standard of public taste. In England how few works showing really high aspirations were to be met with among the thousands of pictures produced every year. This, doubtless, was in a great measure due to their non-appreciation by the public when produced. In Greece and Italy the reverse was the case. The people had the natural sensibility which made them capable of appreciating the noble, the beautiful, and the heroic in conception; and the artists of those countries were obliged to work up to the standard of public knowledge and public taste; and the result was the great works which happily had been preserved, not only for our instruction and study, but also for the delight of cultivated minds through all ages. The lecturer adverted to a feeling some persons entertained that we had no subjects calculated, like the myths and poetry of the Greeks, to afford opportunities for high and beautiful art. This he denied, and spoke of the splendid sources of inspiration to be found in the Bible, both in the Old and New Testaments; grander, he thought, than anything in the mythologies of ancient Greece and Rome; and he hoped that as the public taste improved, these subjects would become more and more studied by the higher class of artists. One

advantage to be derived from education in the principles of art would be to enable people to judge for themselves, and to free them from the dictation of self-elected critics, too often very incompetent to act as guides of public taste. They would then not feel bound to believe a thing to be good or bad simply because they had seen it so stated in print; but, having knowledge themselves, they would understand the true principles upon which to judge the works produced. He was glad that the wish to possess such knowledge appeared to be a growing desire on the part of the public, and he hoped to assist those who favoured him with their presence to attain a knowledge of why some of the works of the great masters, particularly in sculpture, were truly beautiful, and worthy of the admiration that had been so universally accorded to them.

(To be continued.)

## Correspondence.

### INDIA-RUBBER FOR MOUNTING.

SIR,—I have been much surprised at the recent fuss made in some of the journals on the subject of mounting photographic prints with india-rubber. In your article last week you rightly state that its use for mounting is no novelty; it has been used for many years, and if it had possessed any advantages for general purposes would long since have come into use. But the fact that, besides being very expensive, it eventually perishes, is tolerably well-known amongst old photographers. I have seen albums in which the prints, having been mounted by india-rubber, became all detached in a few years, the adhesive gum have changed into a dry, brown powder which crumbled under the finger.

The best material I know for mounting prints on thin boards, without cockling, is glue, used with as little water as possible, and very hot. I always test glue for acidity before using it.—Yours, truly,

AN OLD HAND.

December 20, 1867.

### MAKING A BELLOWS CAMERA.

SIR,—In answer to "W. L. R.'s" (Raepore) inquiry respecting the making of a bellows to a camera, let him make a hollow tube of some thin boards, just nailed together, the width, depth, and length he requires the bellows, procure some twill calico, sew it up the edge on the tube, take the calico off again, and reverse as you would a coat-sleeve, and place on the tube again with the seam underneath the calico; cut some strips of card-board, half or three-quarter inch, according to size of bellows, and a little shorter than the sides of the tube across, with the corners cut slantways, so as to make each piece a section of a pyramid. Then glue them on the calico which is on the tube, alternately, as you see the points in a bellows. I find it better to put one slip on at a time all round the tube than fill one side and turn round to another. When filled the whole length, either paste or glue another piece of calico over the slips and other calico; when dry, take off the tube, and, with the assistance of his fingers at the corners, he will find the bellows to fold up quite easy, as required.

The first bellows I made I did without the box or tube to make it; but I find it much easier with it. I do not send this as the proper method, but as a way that will answer in practice.

If you think the above of any service, insert what you think suitable; if not, give it to the printer's d— to light the fire.—I am, sir, one who is always willing to contribute his mite,

A COUNTRY BUMPKIN.

Macclesfield, December 18, 1867.

## Talk in the Studio.

PHOTOGRAPHY AND BRIGANDAGE.—A comic opera recently introduced to the public, the libretto of which is written by

Mr. F. C. Burnand, revives the recollections of the seizure of Mr. Moens by the brigands. "The Contrabandista"—the name of the piece—represents the doings of a set of ferocious Spanish brigands who have just lost their leader, and, in accordance with one of their laws, the stranger who crosses their path must be elected captain, and marry the late captain's widow. A luckless photographer, wandering in search of the picturesque, falls in with the brigands, and, to his horror, is required to give up the camera for the carbine, and his lenses for a lady. Much of the humour of the piece arises out of these incidents. The piece is performed at the new "St. George's Opera House," Langham Place, under the superintendence of Mr. German Reed.

PHOTOGRAPHS IN AN EXHIBITION OF PAINTINGS.—The hedge of exclusion which has hitherto prevented the recognition of photography as works of art appears to be breaking down. In the Exhibition of the works of female artists, which will open shortly, we understand that a large number of Mrs. Cameron's photographs will be comprised.

CYANIDE AGAIN.—A lady poisoned herself in New York, a short time ago, by taking a dose of cyanide of potassium in mistake for rhubarb. A physician was sent for, but before he arrived she died.—*Philadelphia Photographer.*

A photographic amateur had occasion to use cyanide, and made a solution in the mug used in his bath-room, and out of which it was the custom of his children to go and drink when thirsty. Forgetting it, he left it standing full of the colourless poison, returning just in time to prevent his child from drinking it. Will people ever learn to be careful?—*Ibid.*

STILL ANOTHER APPLICATION.—A subscriber, who is also the leader of the choir in his church, needing duplicate copies of a certain hymn and the inside, soon produced them by aid of his camera, and sends us a proof quite as good as the original. A first-rate idea. What next?—*Ibid.*

ANOTHER CAUSE OF SPOTS IN PRINTS.—Photographers are not unfrequently troubled with black and yellow spots appearing in card pictures which were not apparent before. The following cause is assigned by Mr. Fordos, and confirmed by M. Davanne: Sulphuret of tin is employed frequently in applying gilding to the cards, and particles of this left on the surface of the mount, on coming into contact with the print, will cause spots of sulphide of silver.

LECTURES ON LIGHT.—The "Science of the Sunbeam" was the title of a very able lecture recently delivered by Mr. Jabez Hughes, before the Isle of Wight Philosophical Society, which was illustrated by photographic experiments. We regret that we have not space at present for some eloquent passages we had marked. A lecture on a similar subject was delivered a few evenings ago before the Church of England Christian Young Men's Association, by Mr. George Warrington.

PHOTOGRAPHIC CONUNDRUMS.—We have received the following photographic conundrums as being, we presume, suited for a festive season. No correspondent's name accompanies them, but the writer has appended the phrase, "made by our own idiot out of his own head." Of the idiotry we leave our readers to judge, but we disclaim the ownership:—"What photograph should a young lady never give her intended?—A negative. But if he gets a negative, what should he do?—Take a little sigh an' hide (cyanide). What photographic prints are like the heir apparent?—The Prints of Wales. When is a collector of customs like a photographer?—When he takes port-rates. Why should a photographer use a rolling-press?—To make his portraits flatter. What chemical is like a concealed donkey?—An ass hid. The photographic pirates; what is their little game?—Cribbage. At whist, how do hope to win?—By tricks, and not by honours. What are their winning cards?—Knives. When is their little game up?—When somebody plays the deuce with them."

## To Correspondents.

MIS.—In arranging blinds in such a room as that of which you send diagram, we should make those for the skylight slide with rings from side to side, so that you could have any lateral portion you choose covered or uncovered. We should make the blinds for side-light to slide in like manner, always, however,

sliding from front to back; a cord running through the rings attached to each, and hanging down from the higher end, to be either attached to a hook to hold the blinds in position and prevent them sliding down the rod, which, of course, must be on an incline, or to be furnished with a counterpoise weight for the same purpose.

**CAMERA.**—"The Photographer" is an amateur magazine, as we described in our last, and is only circulated amongst the contributors and their friends. Anything of interest it may contain will be published in our pages.

**W. BARTHOLOMEW.**—Of course the character of the sitter materially affects the possibility of producing pleasing portraits; and the more graceful, striking, or beautiful the model the better will be the picture. The more plastic the model the more easily will the capable artist produce good results; and the more awkward and intractable, the greater will be his difficulty. The more skill and knowledge a photographer possesses the more control he will have even over ungainly and intractable sitters. We have seen many of M. Salomon's portraits of Englishmen, all very excellent pictures. Two of the five gentlemen's portraits we exhibited at Conduit Street were Englishmen. We shall be glad to hear more of the idea to which you allude.

**WATERLOO.**—We are glad to learn that you have found the partial obscuring of your top-light by stippling with white paint produce such a marked improvement in your pictures.

**NON-CHEMICS.**—A combination of oxide of gold and ammonia forms fulminating gold, which is highly explosive and dangerous. Whether any trace of this may have been formed in precipitating your old toning baths with ammonia-sulphate of iron is difficult to say. You may obviate all risk by avoiding drying by heat. A trace of moisture left in the black precipitate will not be a disadvantage in making it into chloride of gold by means of nitro-hydrochloric acid. You will only need to add a little less water with the mixed acids.

**THOMAS STOTHARD.**—The addition of gelatine or of iodine to the developer will not prevent the over-action of light in a window directly opposite your lens in a dark interior. If you cannot cover the window for a time during the exposure, the best remedy will be to paint the back of the plate with red paint, or press a piece of damp red blotting-paper at the back. This will prevent the spreading of the light over the edges of the window. 2. In crystallizing after evaporating by heat, set the solution in a state of super-saturation in a cool place to crystallize; then pick out the largest crystals as they are formed, and repeat the process.

**AN OLD SUBSCRIBER.**—Pure gelatine (Nelson's, for instance) is nearly free from colour, and, in thin layers like varnish, or in tolerably thin solutions, it is practically colourless; but when you speak of a sample "perfectly colourless," we cannot say that we have ever seen such a sample. 2. Chrome alum you can best obtain by writing to Mr. Swan, Mosley Street, Newcastle-on-Tyne. The exceedingly minute trace of it used to render gelatine insoluble renders the colour inappreciable. Common alum, or sulphate of alumina, will render gelatine insoluble.

**X. Y. Z.**—Enlargements by the enlarged negative process can be obtained as sharp as enlargements by the solar camera. 2. Various fluxes may be used with chloride of silver. Mr. Hart's plan of adding half the weight of powdered resin and a little borax is good. That most commonly used is a mixture of the carbonates of soda and potash, twice the weight of this being added to the chloride of silver. It is not very important that every particle of filtering-paper should be picked out. 3. There is no method of saving the gold better than that described by Mr. England, which you will find in our YEAR-BOOK for 1867. It consists in precipitating with sulphate of iron, and boiling the precipitate with nitric acid.

**KENT.**—It is well, for keeping purposes, to preserve your albuminized paper quite dry; but the stock for immediate use may be kept in a dampish place, as over-dessication is attended by many troubles. 2. Waxing prints should be effected after mounting. The wax should be used in a state of thick paste made with an essential oil, such as that of lavender or rosemary. It is roughly applied in places over the print, and then rapidly spread by means of friction with a clean piece of woollen cloth. It is not necessary to have a perceptible coating of it on the face of the print; but if you leave half a print undone, you will quickly perceive the additional richness in the shadows of the part treated. An enamel or encaustic paste for the purpose is prepared by some houses. Newman's have a very good article. 3. In excess of water, chloride of silver is apt to remain suspended a long time. Use as little water as possible, and now and then add a little hydrochloric acid, as chloride of silver is partially soluble in solutions of alkaline chlorides. 4. The decomposition which you describe in the gelatino-iron developer is due to lack of acid, or, possibly, to the use of an impure sample of acetic acid. See Mr. Spiller's article in our YEAR-BOOK in reference to testing acetic acid. Thanks.

**W. F.**—Your phrase, an "illuminated photograph," is scarcely sufficiently definite to enable us to advise you, and your account of the purpose for which it is intended is not sufficiently clear. An illuminated photograph may either consist of positive transparency on glass, or of a positive on paper, made transparent by wax or varnish, and brilliantly coloured. We should fancy you want the latter. 2. The question as to enlarging must depend on the size of the negative and of the print required. 3. In any case, if used by artificial light, it should be placed facing the gas, and be screened a little from light on the side at which it is examined.

**W. J. A. G.**—Hyposulphite will keep in solution before it has been used; but when once it has been used for fixing prints it is liable to change, and should not be used afterwards. 2. You can take open-air groups with your Ross's single lens; it will give you perfectly good and sharp results. For interiors, all single lenses will, however, give curved lines; a double or triple combination is necessary. 3. For interiors or architecture we should prefer No. 2; for landscape and general purposes No. 3 would be better. 4. We prefer a bellows camera. 5. In making or renewing the acetate of soda and gold toning bath no carbonate of soda should be added. 6. Both the samples of cloth are poor, thin, and open. It is possible to get both the twill and the yellow calico closer and better, so that a thickness of each would be opaque enough for a tent. If these are of the ordinary width (that is, three-quarters of a yard wide), they are worth, perhaps, half the price you quote. 7. As a rule, less acid is required in a strong iron developer, because its action being less prolonged, less restraining agency is necessary. If it were necessary to force development by prolonged action of a strong developer, then it would require more acid in proportion to its strength.

**M. G.**—A little thought will satisfy you that when you are using an artificial light to illuminate any single object you waste a large quantity of light, unless you use a reflector, as the light radiates in all directions, only a small portion falling on the object. By using a suitable reflector you concentrate the chief part of the light on the object to be illuminated. To succeed satisfactorily with the magnesium wire you undoubtedly should use some kind of reflector.

**G. G. G.**—The changes which take place in the production of a print by the oxy-hydrogen light are the same as those which take place in the same operation by sunlight. When iodized paper is brought into contact with the bath of nitrate of silver, a process called double decomposition takes place, and iodide of silver is formed in and on the surface of the paper. The action of light upon this sensitive paper is to set up incipient reduction of the iodide of silver, which reduction is completed, in the ratio in which light has acted and commenced it, by the gallic acid, which is in itself a reducing agent, or an agent tending to reduce salts of silver to their metallic form. The object of immersing the print into the hypo solution is to remove all unchanged iodide of silver, which, being still sensitive to light, would, if not removed, cause the whole of the paper eventually to become darkened. The quantity of hypo necessary to fix a print depends, of course, on the size and upon the quantity of silver salt to be dissolved. Speaking roughly, about two sheets of paper may be fixed with one ounce of hyposulphite of soda in five ounces of water. The time of immersion depends somewhat on whether the paper be thick or thin, and the weather cold or hot; but from ten to twenty minutes will generally suffice.

**W. P.**—The diagram E indicates the saucer containing chloride of calcium. Gutta-percha grooves might do, but if much heat were applied they would soften and lose form. Plates should be well drained before placing in a drying box. Thanks.

**JAMES ANDREWS.**—The mistake is doubtless a very troublesome one. The only thing you can do is to get it rectified as early as you can, and avoid using as far as possible the incorrect cards.

**A DABBLER IN THE ART.**—We published all the particulars of the Chassis-Cuvette in our possession. It is not, that we are aware of, made or sold in this country.

**G. M. (Amsterdam)**—The firm you mention sells colour for colouring transparencies, and the work contains hints for colouring glass positives. We do not consider the second work you name trustworthy, especially on the point in question. 2. So far as evidence reaches us, the second you name is as good as the first. Yes; we think so.

Received, "Loaf Prints, by C. F. Himes, Ph.D."

Some Articles and Critical Notices are compelled to stand over until our next.

Several Correspondents in our next.

\* \* All photographs forwarded to the Publisher for registration receive attention at once; but the pressure on our space sometimes compels us to defer the acknowledgment in this column. It should be borne in mind, therefore, that non-acknowledgment at once does not necessarily imply non-receipt or non-registration.

### A FEW MORE WORDS ON INDIA-RUBBER FOR MOUNTING AND TRANSFERS.

SOME further experiments with india-rubber for mounting, and some communications on the subject, suggest a few further hints of importance.

In the first place, on the india-rubber. We find that the solutions formed by various samples of india-rubber differ considerably; some give a solution which always remains semi-opaque and turbid looking; others, no matter how dilute, the solution always retains a dark brown colour. The best result we have obtained was from a piece of india-rubber we received from Mr. Woodbury, which had been purchased, we understood, in Paris. It is apparently prepared expressly for the purpose of solution, being useless for any other purpose in the shape it is kept. It is termed *macerated* india-rubber, and is, in the rough sheet, almost like a piece of coarse woolen frieze. It dissolves somewhat slowly, and a flocculent insoluble deposit is left. After standing, however, to settle, the solution is very clear and light-coloured, a ten-grain solution being of a straw colour, a twenty-grain solution of a deep amber colour. We find that, cut into shreds and just covered with essential oil of rosemary, about a drachm to twenty grains of the india-rubber, a pasty mass is formed, which is readily dissolved on the addition of benzole or highly rectified naphtha. After shaking at intervals for a few hours, the solution should be left to stand to settle, and in twenty-four hours it is perfectly clear. The mixed odour of the benzole and rosemary is far from unpleasant, and the latter, being the most persistent, overpowers the other, and remains longer than the other.

With some samples a twelve-grain of india-rubber solution will be found apparently sufficiently adhesive; but we do not recommend for use a solution containing less than twenty grains to the ounce. Some prints mounted with the twelve-grain solution, in which the surfaces seemed to cohere perfectly, curled up at the edges after lying a few hours in a warm room, and it was found very easy to separate the print from mould. With a twenty-grain solution the cohesion is more perfect; but the attachment is never so firm as with paste or glue. To secure the best adhesion with india-rubber both surfaces should possess a very definite film or varnish of the gum. We have seen it stated that the print and mount, after having been coated and dried, present no change in appearance. This is the case when a very dilute solution is evenly applied, and it is possible to secure some degree of cohesion with such a film, but the attachment is very slight, and easily destroyed. We strongly recommend, therefore, the use of a solution of not less than twenty grains to the ounce; and this should be freely flowed over the surface, not spread as thickly as possible. A thin solution has, in some cases, the defect of sinking into absorbent paper, and produces a mottled appearance.

It is comparatively useless for any one to attempt mounting with india-rubber who has not a rolling-press. Although the cohesion of the two surfaces of india-rubber may be secured by rubbing the print well down, the effect is very unsatisfactory and unfinished-looking. When paste or a similar material is used, the paper becomes softened, and by the contraction in drying, a smooth even surface is secured. When india-rubber solution is used no such result is obtained; the print is not softened, but retains its harshness, nor is there any contraction; the consequence is that any crease, crack, or slight rumpling which may be in the unmounted print shows very definitely in the mounted print, unless by heavy pressure in rolling it is removed. The rolling is, therefore, imperative to secure even a tolerable appearance as well as perfect cohesion.\*

The stability of india-rubber as a mounting material must still, however, be considered doubtful. Dr. Diamond recently called our attention to an album in which photographic prints had been mounted with india-rubber a good many years ago, and which had recently been examined since the idea was revived of using this material. A large number of the prints had become entirely detached and were loose in the book, the adhesive quality of the india-rubber being entirely gone, a dark brown powdery resinous substance remaining on the mounts. In some cases, where a thin solution had been used and had permeated the print, its surface was mottled with irregular brown stains. The prints mounted with india-rubber appeared in no respect more stable than others produced at the same time and mounted with other materials.

A correspondent mentions a recent recommendation, in a contemporary, to use the india-rubber solution as a transferring agent for collodion films, and asks if it can be used with advantage in the simple method of enlargement we recently described as a means of transferring the enlargement transparent positive to paper. India-rubber would have, we fear, a serious defect for any transferring process. The fact which we have mentioned, that it darkens under the action of light and eventually changes into a resinous substance without cohesion, would be fatal to its utility. Few samples are, even at the outset, so perfectly colourless as not to degrade the purity of white paper, and the high lights of the transferred enlargement would necessarily suffer. As an aid to lifting the film for temporary purposes, in any case where the qualities to which we have referred would not be important, india-rubber will doubtless be useful; but we cannot recommend it as the permanent support

\* Since writing the above we notice a letter in a contemporary recommending, in the absence of a press, rubbing down with the edge of an ivory paper-knife. This is a good suggestion, and is of value with a perfectly smooth unbroken print; but if, from curling in drying, &c., there is any rumpling of the paper, nothing but rolling will give smoothness and evenness to the mounted print which the softening effect of the paste and the contraction in drying gives to prints mounted in the ordinary way.

for either collodion negative or positive, as in either case it must necessarily be exposed to the action of light, which produces discolouration, and facilitates the change which destroys its coherent qualities.

### THE USE OF A SECOND STUDIO.

MR. NOTMAN, of Montreal, speaking of the production of pictorial studies by means of photography, recommends all who would excel in this direction to have a second glass-room as a private sanetum for study, in which he may be free from interruption in his special work. Addressing our excellent contemporary, the *Philadelphia Photographer*, he says:—

"One of the greatest luxuries a professional photographer can have, so thinks the writer, is to own a well-lighted sanetum or studio, to which he can retire, and in which he can carry out, without fear of interruption, any fresh ideas which may suggest themselves from time to time. It is not advisable to disturb the studios or rooms in every day use, which, if well appointed, ought not only to be carpeted, but abound in suitable pieces of furniture and choice ornaments, such as are usually seen in drawing or sitting rooms. If possible, let such be real, and so arranged that sitters may have somewhat of a home feeling. The sanetum above referred to need not be carpeted, but be covered with some such stuff as Kamptulicon, which looks so brown and shabby to begin with, that you never fear spoiling it, but as occasion requires, with perfect freedom, pile cordwood on it, build cottages, form sandy beaches with boats drawn up, erect tents, plant trees, crowd solid blocks of ice, form snow-wreathed plains, or, as in the case of the picture for this month, introduce a frozen lake or stream, on which the skater may appear to glide. All this, if it does not afford a change of air, at least gives a change of scenery, and by leading you out of the every-day rut invigorates and refreshes the mind. Do not think that carrying out such ideas involves an outlay of money without any return. In most cases it will be found a very profitable branch to add to any photographic business."

### PRESERVATION OF PASTE, GLUE, ETC., FOR MOUNTING.

ONE of the chief dangers to the permanency of a photograph which can arise from the nature of the mounting material is due to the process of decomposition or fermentation incident to such materials by which acid conditions are generated. Starch and flour-paste and solutions of gum readily ferment; gelatine and gum are apt to decompose. But there is an efficient preventive of either form of decomposition, which, although tolerably well known, is rarely made available by photographers. A trace of carbolic acid prevents decomposition in albumen, gelatine, glue, and similar substances, and will also effectually preserve from any tendency to fermentation paste of wheat flour or starch; and it effects this without in any way altering the qualities of the material, or, like corrosive sublimate and similar agents formerly used for preserving paste, introducing anything injurious to the photograph.

If a few drops of a 10-grain solution of carbolic acid be added to paste or glue when prepared for use, no fear of change or putrefaction need be entertained, as it at once destroys the germs upon which fermentation and decomposition depend. If glue be used it should be tested at the outset for acidity, and a little ammonia added if any trace of acid be present. Most samples of glue and gelatine in the market are more or less acid; the only article of the kind which we have reason to believe to be free from acid is a fine sample of glue prepared by a special process by Bevingtons, of Bermondsey, which doubtless might be brought into the market which supplies photographers, if the demand were created for it.

### A NOVEL HINT FOR DOUBLE PRINTING.

THE charming card pictures of Mr. Edge, especially those with a natural pictorial background, printed from a separate negative, have given rise to a considerable amount of speculation as to their mode of production, and various ingenious theories have been advanced as to how such effects might be produced. Whether Mr. Edge has some secret method of working, or whether the result is due to the skilful application of known methods, we cannot say. In answer to an inquiry on the subject, Mr. Edge stated that his method could not well be described in writing, but requires to be seen to be properly understood. We published a few weeks ago some excellent suggestions from a correspondent as to the best mode of producing similar effects. We now append a letter from a correspondent in Guernsey, which contains an exceedingly ingenious suggestion for a mode of obtaining accurate masks to aid in double printing wherever delicate and careful joining is required. We will print this letter and then add one or two observations on it.

DEAR SIR, — Do you think that pictures might be produced by the following method, similar to those of Mr. Edge?—

1st. Let the portrait be taken with any suitable foreground, but the background must be very light in colour.

2nd. Let a view be taken from nature, or otherwise, upon a dry plate, and, before developing, print the portrait, foreground, &c., upon it, to such an extent as will form a mask, which will, of course, be of the exact form and shape of both figure and foreground, while the part intended to be used as a background will be protected by the light background of the portrait negative, according to its intensity. It may be necessary to retouch the high lights through which the light has not been able to penetrate. Great care will be required in fitting the paper upon the second negative after having printed from the first.

I have not had the pleasure of seeing any of Mr. Edge's pictures, but from what I have read in the *News* this appears to me to be the best way to do pictures of that description.—Yours faithfully,

N. O. MARQUAND.

Fauvert Street, Guernsey, Dec. 30, 1867.

The hint here given appears to be an admirable suggestion for the production of masks. The most careful scissor-work in following the undulations of a fine outline must at times fail; but here we have a means of printing a mask of the figure on the background negative itself. The dry plate containing a latent image, either of natural scenery taken direct from nature, if convenient, or from a transparency taken from an ordinary landscape negative, or otherwise, as may be desired, is still sensitive to light, and when the portrait negative is superposed upon it and exposed to light it will receive another image. The light background, representing the part to be subsequently filled up with a landscape, is in the portrait negative sufficiently dense to protect that part of landscape from further action of light. When the dry plate is developed the landscape will come out without change where it has been protected from light; but where the figure in the negative has permitted the light to pass through, there will be a dense deposit from the double action of light super-imposing one image on another. Where it is insufficiently dense it will be easy to touch upon it with black paint or black varnish, the great difficulty of getting a perfect outline having been already overcome. A perfect mask so obtained, the manipulations in double printing are then reduced to simple matter of mechanical skill and care.

### THE OLD TONING BATH OF HYPOSULPHITE OF SODA AND GOLD.

THE prevalence of faded prints during late years has led to the not unfrequent enquiry, Have we really gained anything in permanency by adopting the alkaline toning system? And there have been some high authorities—Mr.

Heisch amongst the number—who have maintained from the first that theoretically there was nothing in the present system of toning and fixing more conducive to permanency than in the old system, conducted properly. We believe that prints produced by either system, if properly treated, have a fair tenure of permanency; but we believe that the present system is safer, that there is less risk of sulphur-toning and imperfect fixation, than in the bath in which the toning and fixing functions were combined. The fading prints, of late so common, are chiefly due to careless or ignorant treatment in fixing and washing, especially to the repeated use of the same fixing bath after decomposition has commenced.

We are not about to enter into the question in detail, however, now, but simply to call attention to an interesting article by Professor Towler, which we reprint on another page. Our American confrere bespeaks for the old bath of hypo and gold reconsideration, as possessing in some respects undoubted advantage in results over the present method. Alkaline toning processes have the tendency to bleach the prints sometimes in an excessive degree, whereas in a bath of hypo and gold this bleaching process is exercised in a much slighter degree. We wish to suggest to experimentalists who may be disposed to try toning on the old principle, that to be safe the solution should be neutral, and that a subsequent immersion for a short time in strong, fresh solution of hyposulphite is desirable. If freedom from bleaching be the chief advantage desired, that can be perfectly obtained by the use of the toning bath of sulphocyanide and gold, in which no appreciable reduction takes place.

It is to be admitted that the subject of sulphur-toning remains to the present time very imperfectly understood, and that from general experience, rather than from theoretical necessity, it is held in dread. Sulphide of silver is usually of a fine black colour, and very permanent; but the form of it with which photographers are unpleasantly familiar is of an unpleasant yellow, or greenish tint. That this is not necessarily the case we all know: we are familiar with fine black prints, produced many years ago, which remain unchanged now. We have before us at this moment some prints we received from Carl Meinerth, of New Hampshire, U.S., five years ago. They were described as having been toned by immersion for eighteen hours in an old toning bath of hypo and gold made eight months before; and that after fixing they were only washed for one hour. The prints were some of a rich purple, and others a pure neutral black with perfectly pure whites, the prints being vignettes. They were toned just five years ago, and they present no change now: the whites remain pure, and the blacks rich and deep. The permanency seems, indeed, beyond challenge. This is one of many such facts familiar to old photographers, and which render further examination into the causes of such permanency desirable.

#### LEAF PRINTS BY PHOTOGRAPHY.\*

THE sun has been both draughtsman and painter from the time when "the morning stars sang together and all the sons of God shouted for joy;" and "leaf-prints" have been amongst his most favourite works. It was not, however, until the present century that he entered into the service of man to work to order as a draughtsman and printer, and leaf-prints were amongst the earliest specimens of his powers when he entered upon his task under man's guidance. Some of the earliest experiments in securing images on chloride of silver were produced by superposing leaves, lace, and similar objects on the prepared paper, fac-similes of which, in white or a light tint, were obtained on a black ground. Singularly enough, although such a mode of procedure might have many interesting applications, it has received since but slight attention or further development.

\* Leaf Prints: or, Glances of Photography, by Charles F. Himes, Ph. D. (Philadelphia Bennerman and Wilson).

Professor Himes, in a handsome little volume, introduces this mode of working to the public as a valuable aid in the study of botany, pointing out the beauty of its application, and giving detailed instructions for putting it into practice. In an introductory chapter he points out the great value of leaf-prints as an aid to the student. "One great object," he remarks, "of the study of botany is to enable the student to recognize readily the individuals of the surrounding flora, to call them by their names, and to arrange them according to their degrees of kinship. The number and distinctness of the characteristics of a plant, often concentrated in its leaf, and the comparative ease with which the story written in the leaf can be deciphered, make the study of its morphology peculiarly important and interesting to the beginner in botany." The photographic image obtained by printing by superposition—using the leaf as a negative—renders the character of the leaf most perfectly, clearly indicating not only the general formation, but tracing accurately its venation and detailed structure. An admirable illustration of this is given in the photographic plate published in the work, containing a leaf of the *Acer dasycarpum*, one of the common maples of America; a leaf of the *Polygonatum multiflorum*, or Solomon's seal; and an example of the maiden-hair fern, or *Adiantum pedatum*, all printed on one piece of albuminized paper. On the value of the study of leaf-structure, and the facility which photography offers for assisting such study, Professor Himes further remarks,—

But the fronds of the ferns reward in the highest degree the study of leaf morphology. Almost all specific and generic characteristics are found in them, when the nature of the fructification, the shape of the sori, their position, &c., is considered, all of which can be perfectly represented by the photographic method used for the illustration, in which the marginal fructification is beautifully rendered. Thus the plate of this, one of the lower orders of vegetation in our earth's flora in pre-Adamic times, is written in the impressions of its leaves upon the rocks. They tell that during the carboniferous era, when the vast beds of coal were stowed away for the subsequent use of man, the ferns which at present seem only to serve to relieve, by their freshness and beauty, the waste and gloomy places, preponderated in number of species and genera, and in some of their representatives, even in our zone, aspired to the dignity of treelood, as they now only do in the tropics.

One of the most important points in commencing the production of leaf-prints is the selection of suitable leaves to act as negatives, and on this subject Professor Himes gives apt instructions. To secure the most definitely marked results in printing, vigorous leaves gathered late in the season answer best, those gathered in the spring being least intense. The dried leaves of a *hortus siccus* may be used, the specimen-plate having been printed from such; but freshly-gathered leaves give the best results. Here are some hints for the selection and treatment of the leaf negative:—

In gathering leaves for photographic purposes, some care should be taken to procure perfect and characteristic specimens. The margins should be kept as free from overlapping as possible when the leaves are placed in the printing-frame or pressed. Some are more easily managed if very slightly wilted, but generally, the sooner they are subjected to a slight pressure the better. A portfolio or ordinary atlas, supplied with sheets of printing-paper, should be taken to the woods, in which the most delicate one—as the maiden-hair, fine-haired mountain fern, &c.—can be placed as soon as plucked. Many leaves can be printed from without pressing or drying, as forest leaves, many ferns, columbine, anemone, black currant, &c.; but when the pines of the leaf may be expressed by the pressure used in printing, and stain the sensitive paper, it will be necessary to subject them to some pressure between the folds of bibulous paper. They should not, however, be dried as for an herbarium.

The ribs and veins in prints made from undried leaves appear as sharply-defined dark lines, and the whole appearance of the prints is superior to those made from dried leaves in which the ribs and veins are represented by comparatively ill-defined white lines. The maple leaf of the accompanying illustration can therefore be easily surpassed by any reader by printing from a freshly-plucked leaf.

The reason of the difference alluded to lies in the fact, that the ribs and veins, whilst filled with the fluids which they convey, are transparent, and allow the light to pass through and make a record

of them in dark lines. When dry and empty, they are opaque, and, by preventing the action of light, produce white lines.

Dried leaves may be made to give prints in all respects equal to, and sometimes even superior to, those obtained from freshly-gathered ones, by soaking them for several hours in water until the veins become expanded and filled. They must then be pressed between the folds of bibulous paper until dry enough superficially to print from. After this treatment they will only remain in good photographic condition several days, but the operation can be repeated as often as desired. A little glycerine added to the water will cause the veins to remain transparent longer, and a little hydrochloric acid will facilitate the filling of the veins in some cases.

When it is desired to print from several leaves upon the same piece of paper at the same time, it will be found convenient to fasten them to the glass by means of dilute gum-water. Immediately after being fastened to the glass in this way they should be subjected to the pressure of the clothes-clip as in printing from them. In some cases it is best to place the leaves—especially dried ones—between folds of writing-paper, and subject them to as great a degree of pressure as can be obtained by means of an ordinary letter-press, before fastening them on the glass. If the leaves are not of the same intensity, the most intense—those that require the longest time to print—may be bleached as much as necessary by means of Labarraque's solution, or those least intense may be stained light yellow by means of turmeric. Small plants with flowers that preserve their shape somewhat in pressing—as violets—can be photographed entire.

As all prints taken from the leaves themselves must consist of a light image on a dark background, Professor Himes suggests that for many purposes an improved effect will be produced by using the print first obtained as a negative; first treating it with wax, to render it transparent. The following is the method recommended:—Melt some pure white wax by placing it in a shallow dish placed in a pan of boiling water. Immerse in the melted wax sheets of blotting-paper. As these sheets will absorb much more wax than is required, a pile is to be made of (say) half-a-dozen of these with half-a-dozen clean sheets of blotting-paper, placing alternately waxed paper and clean blotting-paper, a few extra sheets of the latter being placed at top and bottom. The whole pile is then pressed with a flat-iron heated to about the temperature of boiling water. By this treatment a series of uniformly waxed sheets of blotting-paper will be obtained. When a print is to be waxed for use as a negative it is placed upon a sheet of blotting-paper, and then upon its face is laid a sheet of the waxed paper; this is then covered with two or three sheets of blotting-paper, and the whole pressed with the hot iron. The negative is thus uniformly waxed, and made sufficiently transparent for printing purposes.

Lucid instructions are given to enable the amateur who is not familiar with photographic operations to print from the negatives so obtained, either by the ordinary silver processes, by the ferrideyanide of potassium process or the bichromate of potash process. With each of these processes most practical photographers are familiar. We may, however, briefly mention here the formula for the two latter. The first of these gives blue prints. Prepare,—

Ferrideyanide of potassium (red prussiate of potash)	...	...	...	...	100 grains.
Water	...	...	...	...	1 ounce.

Apply the solution with a tuft of cotton to a piece of *Saxe* paper pinned to a board. This will give paper of a uniform yellow tint. This, on exposure to light, becomes blue; the only fixing process necessary being copious washing in water until all trace of yellowness is removed. A saturated solution of bichromate of potash produces brown images by similar treatment; excess of washing having a tendency to decompose the image of brown oxide of chromium, and leave a pale green image of sesquioxide of chromium.

This volume opens out to amateurs in various studies a new means of preserving examples and patterns, and to botanists especially, suggests a method of study elegant in itself and invaluable as an aid to systematic progress.

## Critical Notices.

THE PHILADELPHIA PHOTOGRAPHER. Vol. IV. 1867. (Philadelphia: BENNERMAN and WILSON.)

THERE is no contemporary photographic journal which we take up with so much pleasure as the *Philadelphia Photographer*; none in which we are so certain to find something which will well repay reading; it is, in fact, altogether a model of what a monthly photographic journal should be. The energetic and able editor, Mr. E. L. Wilson, is already assisted by many of the ablest writers on various departments of photography, and we note that he has just strengthened his staff by the accession of Professor Towler, formerly editor of *Humphrey's Journal*, who will now contribute regularly to the *Philadelphia Photographer*. Amongst the writers whose valuable articles have aided in giving interest to the volume just closed, we find, besides that of the Editor, the names of Carey Lea (whose researches generally first appear there) Dr. Vogel (who is German correspondent), the Rev. J. H. Morton, the Rev. A. A. E. Taylor, Professor Henry Morton, Coleman Sellers, J. C. Browne, F. A. Wenderoth, C. W. Hull, G. Mathiot, Professor O. N. Rood, J. Zentmayer, J. Q. A. Tresize, Dr. Liesegang, and many others, all of whom contribute excellent original articles. A very interesting feature of this journal is the publication each month of a photographic picture illustrating some point of interest. A number of very capital cabinet pictures appear, amongst other subjects, in the present volume, and have, we doubt not, helped to popularize its picture and secure its success. The question has at times been asked by some of our correspondents as to whether we could not occasionally issue examples of processes in our pages, and we have had to regret its impossibility, as the cost of almost any form of mounted photograph would exceed the wholesale price for which a copy of the *PHOTOGRAPHIC NEWS* is sold. In America a different state of things prevails. Photographic literature is not there nearly so low-priced as in this country. Here the standard price for a manual of instructions in photography is one shilling; there it is one dollar, or four times the amount. The price of each number of the *Philadelphia Photographer* is half-a-dollar; but we consider it cheap at that sum, and commend it to any of our readers who, in addition to excellent information, would like to see a good example of photography every month by a first-rate man.

We may add here that our esteemed friend, the Editor, has made arrangements to send us advance proofs of any important original articles which appear in his pages, so that our readers will have the earliest access to any interesting matter in connection with photography transpiring amongst American photographers.

ON THE PRODUCTION OF PHOTOGRAPHS IN PIGMENTS: Containing Historical Notes on Carbon Printing, and Practical Details of Swan's Patent Carbon Process. By G. WHARTON SIMPSON, M.A. (London: THOMAS PIPER. Newcastle: MAWSON and SWAN.)

FOR obvious reasons we cannot enter into any notice of this work beyond noting the fact of its issue, and briefly mentioning its contents. After a brief *resume* of the history of carbon printing from its origin until the present time, the chief part of the work is devoted to a minute statement of the practical details of all the operations in Swan's carbon printing process. These instructions are based on a careful observation of the operations in the Newcastle carbon printing establishment, and upon observations during much personal experiment and practice; and they are moreover made authoritative by having undergone Mr. Swan's examination for verification or revision.

There are, also, chapters on the theory of the action of

light on chronic salts and organic matter; upon the selection of the various materials used; upon colouring carbon prints; upon Faults, Failures, and Remedies, and other subjects of interest connected with the process. The frontispiece to each copy is a very fine example of carbon printing from a negative, in some cases by Robinson, and some by Faulkner.

#### THE YEAR-BOOK OF PHOTOGRAPHY for 1868.

Edited by G. WHARTON SIMPSON. (London: PIPER and CARTER, Gough Square.)

A YEARLY resume of the progress of photography and an epitomized statement of materials have grown to be necessities amongst photographers, as the eager demand for the YEAR-BOOK OF PHOTOGRAPHY illustrates. We cannot, of course, speak here of our own part in producing the work; but we may speak with pleasure and pride of such an array of contributors of original articles of current or permanent interest, such as has rarely, if ever, been brought together in one work. Besides a restatement of the principal processes in constant use in the forms in which they are now practised by the ablest authorities, and synopses of the best formulæ, and of the new and modified processes of the year, here are upwards of forty original articles by various contributors, of the titles of the principal of which a brief recapitulation may be interesting. Mr. Francis Bedford treats on landscape negatives and some hints for their improvement; and there are few men in the world whose dictum would carry so much weight on the subject. Mr. Mudd writes on art knowledge and photography, and all the world knows that in writing of art and photography he is speaking of something which his practice shows that he thoroughly understands. Mr. Robinson points out, with caustic force, common fallacies concerning photography, in which both photographers and the public indulge. Mr. Hughes describes a new method of reducing the intensity of negatives, with a practical authority that carries weight. Mr. R. Manners Gordon describes a dry process, the plates by which, whilst very sensitive, and yielding negatives of rare excellence, have perfect keeping qualities. Mr. Blanchard has several excellent contributions, all on interesting subjects, and valuable as arising out of his own practice. Dr. Anthony describes a capital dry process. Mr. Spiller gives a most useful chapter on the detection of impurities in photographic chemicals. Mr. Swan describes a method of transferring carbon prints without the aid of a press, which will be invaluable to amateurs. Mr. Dallmeyer treats on lenses; Mr. Fry on keeping negatives; Mr. Cherrill on photographing machinery, and on the sulphocyanide toning bath; Mr. Werge gives hints on copying Daguerreotypes; Mr. Bovey, the preservation of sensitive paper; Mr. A. Keene, on dry plates; Mr. F. G. Eliot, on a successful method of reducing overprinted proofs; Mr. J. Eastham, on harmonizing contrasts and shortening exposures, and, also, on retouching negatives; the late M. Claudet, on a unity of measure, for use in enlarging; Mr. England, on his experience in commercially working his new dry process; Mr. H. Cooper, on preserving and improving prints by paraffine; Mr. Woodbury, on transferring negatives; Mr. H. B. Pritchard lays down the conditions of non-success; Mr. A. Hughes gives a curious experience in printing; Mr. Mawdsley, a chapter of instructions for alkaline development; a capital printing and toning process is described by Mr. M. Whiting; Mr. J. R. Johnson has some excellent hints on copying and enlarging; Mr. Cuthbertson gives some simple calculations, suggesting a ready way of ascertaining approximately the angle of view included by a given lens; and Mr. Burgess describes a simple drying box. These are some of the subjects treated, and may enable our readers to judge of the interest of the work.

#### ANOTHER NEW DRY PROCESS.—SOAP IN COLLODIO-BROMIDE OF SILVER.

MR. CAREY LEA contributes to the January *Philadelphia Photographer* some interesting details of experiments in dry-plate photography, which, by the courtesy of the Editor, we are enabled to lay before our readers early. The object of his researches is to secure the two valuable conditions of greater sensitiveness and more simplicity in preparation; the least complex of the dry processes in use involving, in his experience, manipulations at least twice as much work as the wet process. "It was, therefore," he remarks, "with a view of finding something simpler and more convenient for my own use that I set to work to experiment. After some consideration I selected Messrs. Sayce and Bolton's ingenious collodio-bromide process as the best basis for experiment, and set out to find whether it could not be possible to obtain a substance which, simply added to the collodio-bromide, would act as a preservative. If this could be done the whole labour of preparing the plate would be reduced, after the collodion was poured on, to a simple washing and drying.\*

"I soon found that a variety of substances would produce the desired effect. With benzoic acid I obtained a tolerable result. My next step in advance was in the use of shellac varnish. I had previously observed that shellac in solution gave a precipitate with nitrate of silver, and that this precipitate was sensitive to light. I therefore added a few drops of lac varnish to the collodio-bromide mixture, and obtained a tolerable picture.

"Gum guaiacum contains a considerable quantity of an acid termed guaiacic acid, which combines with silver. The introduction of tincture of guaiacum with the collodio-bromide was found to give rather better results than the last-mentioned substance, but, as a still better agent was obtained, experiments with it were discontinued.

"Several years ago it occurred to me that oleate of silver, in view of its sensitiveness to light, might become valuable in photography, and as far back as 1863 I made various experiments with it, which are referred to in passing, in an article I published in the *Philadelphia Photographer* for February, 1864. I therefore concluded to try this substance in connection with the collodio-bromide, and found it to give results much better than any of the preceding, especially when used together with camphor. I obtained, in this way, very satisfactory results. Every part of the process is easy and simple. As the preparing a solution of soap in alcohol is somewhat troublesome, I avoid this objection by using an official tincture, which can be procured anywhere, and is always ready. The details are as follows:—

##### COLLODION.

Alcohol . . . . .	1 ounce
Ether . . . . .	1 1/2 "
Bromide of cadmium . . . . .	4 grains
Bromide of ammonium . . . . .	3 "
Camphorated tinc. of soap . . . . .	5 minims.

A supply of this should be made and put away for at least a week to ripen.

"Grind some nitrate of silver to a very fine powder; it must be, not like a fine sand, but like flour, perfectly impalpable. This should be done in a perfectly clean mortar; an agate mortar is best for all such purposes, and will be found a useful adjunct to every experimental photographer's apparatus. Weigh out 40 grains of this pulverized nitrate, and add to it 3 ounces of the collodion. Shake up thoroughly at intervals for about four hours, after which either filter through sponge in a common collodion filter, or let stand five or six hours to subside; I prefer the former method decidedly.

\* At the time I made these experiments, I was not aware that Mr. Sayce at one time had suggested the employment of tannin in the collodio-bromide. He seems to have abandoned the idea, as in his communications for some years past he has not referred to it. My preservative agent is very different, and my plates retain their sensitiveness after a thorough washing, thus giving every reason to expect thoroughly good keeping qualities.

## MODE OF OPERATING.

"Edge the plate with 1-grain solution of rubber in benzole, or with dilute albumen (white of 1 egg, 4 ounces water, 30 minims liquid ammonia, and filter through cotton or paper). The former is the least trouble, because the plate can be collodionized at once; if albumen be used, it must, of course, have time to dry. Collodionized in the usual way, let stand about two minutes, during which time the next plate is edged with benzole-rubber varnish, and then put the plate right under the tap, provided with a rose to scatter the water; move it about till the water covers the plate freely, and then leave it about five minutes to wash. A tube like an inverted **L**, with a cork in the upper end, to slip over the faucet, and holes punched underneath the bottom at both ends, enables one to wash two plates at one hydrant. This is very convenient for all washings, but especially in the present case, where the plates are so quickly made, and come in so fast to be washed.

"After washing, the plates need only to be dried, and are ready. As to their keeping qualities I am not yet able to speak, as I have tried none longer than a week; but these were not in any way impaired, and there seems every reason to hope for at least an average permanence, or probably more, as everything soluble is, in this process, removed from the plate.

## DEVELOPMENT.

"This is the regular alkaline development. The form that I have used is,—Moisten with water, and, when equally wet, apply a 1-grain solution of carbonate of ammonia, adding to it a drop or two of a 10-grain solution of bromide of potassium, and a drop or two of a 60-grain solution of pyrogallie acid in alcohol.

"As the image comes out, add more pyro, giving plenty of time; a little of a stronger solution of carbonate of ammonia may also be added. If sufficient density is not obtained in this way, wash off, pour on dilute acetic acid; pour this off after a minute or two, and add it to plain pyro, with a little solution of nitrate of silver 15 grains, citric acid 15 grains.

"This process gives plates rather more sensitive than the coffee process, and has the advantage of being materially less trouble.

"P.S.—Further experiments, made since the above was in the printer's hands, showed that an alcoholic solution of aloes gave still better results. The best proportion has not been ascertained. The aloes are boiled with alcohol in a test-tube, and a few drops added to the collodion instead of the tincture of soap. Probably commercial tincture of aloes will be found to answer equally well.

"Further experiments are in progress, and the results will be communicated. The exact determination of the relative values of different sensitizers is laborious and troublesome. The whole subject is one that gives a great opening for experiment."

## AGAINST THE USE OF DISTILLED WATER FOR PHOTOGRAPHIC PURPOSES.

BY NELSON K. CHERRILL.

I LOOK upon *distilled water* as one of the greatest mistakes of the photographic laboratory. It is, I believe, quite useless in all the useful operations of practical photography. For the purposes of scientific experiment, for elaborate comparisons of the respective values of certain solutions, for a few unimportant dry processes, and for those who believe in *hand-books* and *books of instruction*, distilled water may be found an indispensable necessary; but in the ordinary course of photographic work I do not find any advantage gained by its use, or any disadvantage to accrue from substituting for it the ordinary water as it is "laid on," which is of course much cheaper, and which serves every purpose.

The water which is supplied to me now contains, I doubt not, a most delightful list of impurities, and these abound in sufficient quantities to render it exceedingly nice to drink

(a sure sign of great impurity), and to throw down a great milky-white precipitate with nitrate of silver; yet I use it for making nitrate baths, and for every other photographic purpose, with great success.

For the nitrate bath, the most delicate of all the solutions used by the photographer, nothing more is required with this or any other sample of similar water than the addition of a few grains of silver to a gallon or so, or an ounce of old bath-solution may be thrown into a considerable bulk of the water. The precipitate formed may be, if thought well, collected on a filter, and the paper added to the silver-waste box, or the precipitate may be thrown away; the bulk of it will fall to the bottom of the vessel in which the silver was added to the water, and the slight amount which remains in suspension may be disregarded.

For the developer I never find the slightest difference in effect between one kind of water and another. It does not seem to matter at all about the precipitate formed by the silver in the water; indeed I am not sure it is formed at all, the sulphate of iron decomposing the nitrate of silver before it has time to effect the precipitation in the water of which the developer is made.

I have never been able to see the least use in washing the film with distilled water after the hypo has been all removed from the film. This is recommended by some as a means to remove the impurities of the common water, and so to enable the shadows of the picture to dry more clear and brilliant. I have never found a negative print any the better for all this extra trouble.

I find a bath for printing purposes may be made just in the same way as that recommended for the nitrate bath; i.e., the water cleared first with a little silver, and then filtered or left to settle. I have never made a toning-bath with distilled water that I can remember, and so I cannot speak from experience of the difference (if there is any) between common water and distilled for this purpose; but I never find the slightest fault with my toning baths; they do their work quite well, and that with common water.

I have thought much upon the use of common water for dry plate washings. I am convinced that distilled water is not at all required in any of the best processes. The precipitate from water is only an insensitive silver salt, generally chloride; how should this hurt the film, which always contains bromide and iodide of silver, and often chloride too? It seems to me that the more a dry process depends on some abnormal condition for success the more need there is for using distilled water. I have noticed this particularly with the tannin process. I have done some very good pictures with tannin plates, but of all the processes I ever tried it is the most *uncertain*; success seems to depend on some curious abnormal conditions which no one understands, and the most trifling disturbance, even one so small as that caused by the minute quantities of foreign matter in common water, is fatal to good results. Turn to the other extreme; the most *certain* of all dry processes—the collodio-albumen—to use Mr. Mudd's own words, "distilled water is not necessary in any stage of this process." These things may not be fully understood yet, but till they are, I say, give up those processes which need distilled water, because they depend upon *uncertain conditions of success*.

## RECENT EXPERIMENTS WITH COLLODION.

THE results of the experiments detailed by me in my last paper were:—

1. That strongly-iodized collodion was more sensitive to sombre rays than a weakly-iodized compound, and yielded, therefore, more harmonious and softer pictures.

2. That weakly-iodized collodion gave harder pictures, which were liable to become fogged by the employment of a strong developer.

The conclusions which may be drawn from these results are obvious. If softness and sensitiveness are required, a

strongly-iodized collodion should be used; but if greater contrasts are desired (as in the case of dimly-lighted landscapes), a collodion containing but a small proportion of iodizing salt should be used, together with a weak developer, in order to prevent fogging.

Many would conclude from these circumstances that, in the reproduction of drawings or designs made up of minute lines only (in which, therefore, there is no half tone), a weakly-iodized collodion would be best adapted to the purpose; but this is not the case. My experiments were made with a strongly-lighted object (a white plaster bust), whereas drawings are reproduced in such a manner that only a weak image of the same is shown in the camera, the whitest description of paper appearing in such pictures darker even than black drapery in a photographic apparatus. It stands to reason, therefore, that the collodion which is least capable of yielding an image of the black drapery is not sufficiently sensitive for the reproduction of drawings which depend for their perfect formation chiefly upon the obtainment of opacity in the white of the negative. I have already called attention to this fact, and have found by experience that in the reproduction of poorly-lighted objects a sensitive collodion gives the best results.

I will now continue the result of my researches. After the institution of my experiments with iodized collodion of a thick and thin consistence, I believed that similar results would be obtained in working with thin and thickly-poured collodion films; two plates were coated, therefore, the one very thickly and the other as scantily as possible, and placed together in the dipping bath. A portrait was taken on each of the plates, and both developed as nearly as possible in the same manner. The difference in the results obtained, although not very great, was nevertheless observable; both showed an equal amount of detail, but in the thinner film the lights were a little more intense and the shadows slightly weaker than in the thicker one, giving the former negative a more brilliant appearance, without any loss of delicacy. The result of this experiment affords a reason why many portrait-photographers, who have a good eye for gradations of light and shade, are in the habit of using a collodion of a thin consistence.

But how is the phenomenon to be explained? At first sight, one would think that as a thick film of weakly-iodized collodion no doubt contains about as much iodine and bromine salts as a thin film consisting of strongly-iodized collodion, the result in both cases would be nearly identical. That such is by no means the case is shown by the above experiments; for a plate prepared with weakly-iodized collodion proved itself to be much less sensitive than a thin film of the strongly-iodized material. The explanation of the matter lies, most likely, in the proportion that the gun-cotton bears to the iodizing salt; this is obviously double as large in the weakly-iodized material as in the strongly-iodized collodion, and to this circumstance is, no doubt, due the inequality which exists in the sensitiveness of collodions.

(To be continued.)

## ARTISTIC PICTURES PHOTOGRAPHICALLY CONSIDERED.

BY E. DUNMORE.\*

THE difficulty of selecting the title of a paper will, I trust, be considered sufficient excuse for occasional digression from it. The sweeping criticisms to which any photographic picture is subjected that aspires to be something beyond an ordinary matter-of-fact photograph is patent to all, and has the effect, no doubt, of damping the ardour of many an ingenious and artistic photographer. It is all very well to say, "Spare the rod and spoil the child;" at the same time, too much rod is a bad thing.

It would be disparaging the ability of a class of men whose mechanical ingenuity is well known, to suppose for an instant that there are not many perfectly able to do all the *necessary manipulations* of, we will say, a composition picture as well as it is possible to do it, and as well as it has been done. This admitted, the other condition—undoubtedly the most difficult one, and may, perhaps, be considered as *the difficulty*—is that of finding men sufficiently artist to design, as well as possessing the power of embodying their ideas in the anything but plastic envelope of photography. That there are great difficulties must be readily admitted, when we consider that the proper knowledge necessary to success includes the thorough acquaintance with many arts and sciences which will dovetail as they do so intimately one into the other.

How is it we see so few good composition pictures when many real artists are themselves photographers? Is it because of the difficulty attached to the work, or that the results do not repay the trouble, or both combined? One thing, as yet composition pictures are but a beginning of what will be when our attention is more especially directed to the art rather than to the necessary manipulations, almost the synonym for a photographer. Even now hundreds are capable of making perfect negatives, when but a few years back not one in a hundred could do so; eventually but few in the profession will be unable to produce perfectly-manipulated pictures. Then photographers will not be judged of so much by faultless workmanship as by the skill displayed in the design and composition. The foundation of our pictures will then be based on the most solid principles of art. The fashion with many, of planting their cameras almost haphazard where there may be pretty scenery, or what not, will become obsolete, and outrages upon every art axiom, now so plentifully scattered about, will, in a great measure, cease to be, and photographic pictures will gain in quality what they lose in quantity.

How shall he go to work to hasten this most desirable state of affairs? I may say, "What shall we do to be saved?" Keen competition and low prices are decidedly adverse. It is not an inducement to spend one's time and money upon what will be, after the most lavish expenditure of care and skill, hawked about for a few shillings. One great and good thing now, as far as we can determine, is the possibility of rendering our pictures permanent, which demolishes at once the most forcible objection—that of fading away. Before we could do so few would be inclined to invest their money largely in what, although a thing of beauty, was not a joy for long, frequently but for a month or two. Now it is different. Given the requisite negative, a permanent impression can be made exceedingly beautiful, and delicate as a refined painting. Why, therefore, should not a photographic picture, skilfully composed (I say this advisedly) and made permanent, be as valuable as another monochrome drawing by another process? I feel confident that were more attention given to the *art* qualities of photography, a greater number of composition pictures would be the result, and truth would also more frequently be combined with beauty. At the same time, I do not presume to place photography upon an *equality* with painting, or as a rival to other *coloured* works of art; for we all know that colour, judiciously applied, will of itself go a long way in making a picture, as the inspection of many of the gems of celebrated colourists will testify. Instance many of the figures in Turner's pictures, which are wretchedly drawn, but most skilfully and judiciously coloured, so much so that the ill drawing is entirely overlooked, the colour and general effect engrossing the whole attention; therefore the absurdity of placing them in comparison. As Opie observes, in alluding to colour, it is the "sunshine of art, that clothes poverty in smiles;" but, unfortunately, we have to apply sunshine in another manner.

The general depression in the photographic trade-profession is undoubtedly owing, in a great measure, to want of novelty. One good photograph repeats another so much,

\* Read before the North London Photographic Society, January 1st, 1867.

in general appearance, as to be monotonous, and the best of them are slightly remarked upon as "only photographs." That the family likeness is strong there is no disputing; and if photographic pictures are to become intrinsically valuable as works of art, it is evident that the true pictorial element must be more thoroughly amalgamated with them, so that they will be exponents of the thoughts as well as of the manipulative skill of the individual photographer. Photographic pictures, broadly speaking, should be an assemblage of lights and shadows, so as to form large masses of tints (*vide* Salomon); these, again, divided into smaller masses, until every appearance of contrivance is lost, and the whole together takes that harmonious and artless appearance which so exclusively belongs to natural arrangements. At the same time the whole picture should be subjected to the first intention, that whatever impression or sentiment was to have been conveyed is fulfilled in all things in the picture working together for one end. Unless the photographer does this he had better leave composition photography alone.

With many other professions periodical meetings are held, and rewards, in some form or other, are given for the best productions. The Sketching Club is an instance of the successful working of this plan, and its arrangements undoubtedly tend to increase a love of the art for itself. Why could we not do something similar in addition to our ordinary meetings, and let these be increased to every month throughout the year? I believe it has been suggested, but nothing as yet has come of it. We are certainly dependent upon daylight for our work, and could not manufacture a picture by candle-light in an hour or so; but we could exhibit pictures made from some special suggestion in the interval between the meetings. I am, of course, presuming that the theoretical, and some practical, knowledge of drawing would be part of the stock-in-trade of each member, and who would be expected to contribute a picture at each meeting, worked out from the suggestion given. The details of such an association, of course, requires consideration. I merely suggest, or re-suggest, the broad outline of a plan I believe would be attended with good results, would be worth a trial, and give an impulse to an unmistakably languishing profession, by making the production of good pictures a matter of friendly rivalry and love of art, rather than exclusively one of profit. The profit would, however, be a natural consequence before long. Again, a common idea is that photography can only achieve as much as it has done—can, in fact, be no more than a mechanical process. New apparatus can be made and applied in new directions; we may improve definition and straighten the lines, but as to real advancement, from an artist stand-point it is out of the range of possibility.

Composition pictures are certainly the most daring attempts to burst the bounds of what is considered the limits of a process, and are attempts worthy of imitation by all. It is not, however, to be expected that we could produce lovely faces and figures as a skilful painter could imagine, with all the lofty supernatural beauty denied to us mortals. Fact, uncompromising fact, is what we have to deal with, and we must confine our attention to material subjects, and in the varied and beautiful forms of nature find employment for our cameras. Being denied the ideal, and limited to earthly subjects, we must make up by light, shadow, and general outline for the deprivation. Much may be done, quite enough to allow a wonderful advance upon the present state of our particular craft.

Light and shadows are our sheet-anchors. A clever arrangement of the chiaroscuro, and a few touches, will make a picture, when myriads of touches and bad lighting will make a photograph the derision of everyone who knows anything about art, perfect, perhaps, in its chemical aspect, but horrible in its pictorial one.

It is evidently labour in vain to attempt to imitate the beautiful faces and forms of a Raphael or a Guido; but we can make a picture full of sentiment and beauty from the

material we have at our command. A difficulty certainly exists in getting suitable figures, and in using them, when we have got them, to the best advantage. Our landscapes are always beautiful, and do not lack variety, and the time may come when paid living models will be as necessary to the landscape photographer as to the painter.

If the production of high class clever pictures were so easy, their value would of course be less. The greater the difficulty of production the greater the worth. When we see a beautiful result we are apt to overlook the time, care, skill, energy, and battling with almost insuperable difficulties necessary to its production: the result is all we know, if it be good or bad. If good, no one can imitate it without undergoing the same ordeal to procure the negatives. The very difficulties enhance the value of the work, and, as I have before said, I believe the fewness of really good works causes the popular idea that photographers are incapable of doing better.

The productions of many of the great painters supply to us admirable studies of the proper balance of light and shade to which I have before alluded as of the utmost importance to the photographer.

I may here mention that the extraordinary power which the eye possesses of excluding all other things when bending its greatest strength of vision on any particular object, or part of an object, is highly interesting, and may be considered as the leading principle upon which chiaroscuro is based. The contrast of light and shade by which both seem to be increased in intensity when in near proximity one to the other is a quality in the laws of vision most invaluable. We may gain much by studying the activity of the eye; its conclusive mode of reasoning, or rather the vast power it has when cultivated of forming true conclusions, apparently without the necessity of reasoning proceeding from that power, we may call unconscious knowledge. The careful study of these things will confer much more real benefit than the commonplace attentions they usually get, for upon these niceties of light and shadow the picture has solely to depend for all that is to give life and piquancy to that portion of effect that comes under the head of chiaroscuro. Many pictures will show, upon careful inspection, certain principles most carefully observed by each master. Amongst those to whom I would specially call attention as being most suitable for the study of the photographer are works of Rembrandt, Corregio, Rubens, Van Steer, Tenier, Ostade, and Ruysdael. Rembrandt, for instance, usually makes a great mass of shadow serve as a foil for a small quantity of light; Claude *vice versa*. We may recollect, in Rembrandt's works, clever arrangement of the chiaroscuro constitutes one of the principal beauties of his pictures. Ruysdael, too, whose pictures of Nature in her more sombre moods are most beautiful—you cannot look at them without feeling their power and truthfulness; in fact, the study of our national pictures ought to be the care of every photographer.

Photographs are representations of reality, frequently too real to be beautiful; but by well managing the light and shade, and by the judicious introduction of figures, a work may be produced that will be the link between a drawing by hand and the more elaborate oil-painting—a source of gratification to lovers of true art, and of profit to the artist. We have numerous instances in which the drawing and chiaroscuro are sufficient to make a notable work of art even when the colouring is but indifferent. This fact alone proves we have the power of making pictures if we only properly apply it. We must not forget that any one can, by practice and attention, produce perfect chemical results; but it requires a real love of true art, and a just appreciation of the beautiful (qualities that may be obtained, more or less, by study), to be able to make a picture. This is the real secret of successful picture-making. This is the quality that can never be brought to such a degree of perfection as to be unimprovable; the more it is elaborated the wider seems the scope for improvement; each stage of advance but seems to unfold others before unthought of; and, to quote

an old-fashioned rhyme, perhaps a trifle vulgar, but appropriate,—

"Each big flea has a little flea  
Upon his back to bite 'un;  
Each little flea has lesser fleas,  
And so ad infinitum."

Intimating that each little knowledge not only adds to the general store, but begets other knowledge before hidden and unthought of. We should therefore give our attention more particularly to the art of *picture-making*, and not let the manipulative part monopolize quite so much of our thoughts as it has hitherto done, but bring ourselves to consider the means as inferior to the end; and we shall yet produce tangible proofs that photography is not only a mechanical-chemical curiosity, but the means of producing truthful, beautiful, and artistic *pictures*; and the year that we this day enter upon will be to all, both photographically and socially, a truly progressive, prosperous, and happy new year.

### RESUSCITATION OF THE OLD TONING AND FIXING SOLUTION,

AND THE TREATMENT OF THE SOLUTION WHEN EXHAUSTED  
OR SATURATED.

BY PROFESSOR JOHN TOWLER, M.D.

It requires more than ordinary boldness and a daring disposition to give countenance to a condemned fashion, a cut of coat out of date, or an ostracized actress. The same boldness and daring will scarcely preserve us unscathed when we assert that, in our humble opinion, the old toning and fixing solution, consisting of hyposulphite of soda and chloride of gold dissolved in water, is equal, if not superior, to any other toning and fixing solution now in vogue. This assertion is not founded on fancy, on a mere desire for change, on eccentricity, but on the result of numerous practical experiments; from these experiments we deduce (subject, of course, to amendment, change, or revision, according to the development of further results) that the toning and fixing solution of hyposulphite of soda and chloride of gold is more economical, more certain in the production of a given tone, and more easy of manipulation than any of the other toning and fixing solutions. It remains to be seen whether, by the slight modifications introduced, there are no drawbacks in the way of the prints turning yellow, after a time, by exposure to air or moisture; other faults or disadvantages we do not anticipate, nor do we regard the more rapid exhaustion of the fixing powers of the hyposulphite solution of any account or moment; in fact, some photographers never use this solution more than once; and we have ourselves frequently made this recommendation. Let this advice, however, be recanted, for we find that the solution can be used repeatedly before it becomes saturated with chloride of silver; and, until it is saturated, it is operative of good and uniform results.

Before we give the exact formulæ for the preparation of the toning and fixing solution, it may be well to discuss, in a few words, the separate toning functions both of hyposulphite of soda and of chloride of gold (for the former is just as much a toning re-agent as the latter), and then to examine the results when the two are combined.

In the first place, let a print, when taken from the pressure-frame, be well washed in several changes of water (in the dark room, of course), and then immersed in a strong solution of hyposulphite of soda. You are all familiar with the almost instantaneous change of tone produced on the print, from whatever shade of colour it may previously have had, to a very *light chestnut*; this chestnut hue is the separate and independent result of the hyposulphite of soda, and it has been adopted by Beyse and Joss as the fundamental flesh-tones in their patent\* for producing colours on prints by development.

If the print be not previously washed, but removed

directly from the pressure-frame to the soda solution, the tone produced is somewhat darker; it is still, however, a chestnut hue—a *dark chestnut*. The soluble silver salts in the print have combined to produce the slight modification of hue from a light chestnut to a dark chestnut. But the dark chestnut hue is not produced instantaneously; it requires several minutes, probably a quarter of an hour, the length of time required to fix the print; that is, to remove the chloride of silver in the print that has not been modified by the action of light. During this quarter of an hour the well-washed print retains the same light chestnut tone which was produced the moment it was immersed. Hypo-sulphite of soda, therefore, alone produces on a silver print a *chestnut-coloured tone*, and at the same time dissolves out all the unchanged chloride of silver: this is its fixing property.

Now let us see if a solution of chloride of gold has any effect upon a silver print, either on collodion, on albumen, gelatine, or plain paper. We all know that this solution has been recommended as a means whereby to intensify a negative; and whilst performing this operation we have observed how the tone of the negative *gradually* changes from the grey-white of the silver picture to an *inky* hue; if the solution be strong, the change is very rapid, almost instantaneous. The intermediate tones, before the ink-hue has been attained, are more pleasing, because more warm, being a varied mixture of red and blue. The same result is observed when a paper-print is immersed in the gold-toning solution, consisting simply of neutral chloride of gold. If carbonate of soda, phosphate of soda, citrate of soda, acetate of soda, or chloride of calcium, be mixed with the chloride of gold, we have the result of the two combined, which is slightly different from that of the gold-salt alone. But if we examined carefully, or observed accurately, we must have seen that the gold-salt not only changes the tone of the silver print, but seems also to exercise a bleaching influence upon the colouring matter of the print. This property is observable both on the negative and on the print; and it is to this pernicious effect that we attribute, or may frequently attribute, the improper and unseemly contrast of excessive black and white on prints: they have been bleached, the extremely fine markings have all disappeared, the middle tones have become very faint, and the inky blacks alone predominate. We are inclined to think that, in every case of substitution under similar circumstances, a part of the print must be lost. Here gold takes the place of silver; and, where the markings or shades are very fine or thin, it is natural to suppose that the silver, as it retires all at once, carries with it, as it were, in a vortex, the cause or substance that attracted the gold. But we are beginning to theorise, which was not our intention. The separate and independent action of chloride of gold on a silver print, then, is two-fold: it tones the print, and bleaches it. The final tone is that of an *inky blue*.

Let us now examine the results of the combination of these two toning materials on a silver print. There are two cases: the one is when the print is submitted to the gold solution first, and then to the hyposulphite of soda afterwards; and the other is when the print is immersed in a mixture of the two solutions at the same time.

It is a law in mechanics, that the resultant of two or more forces is the same, whether the forces act separately or co-simultaneously; in chemistry it is very probable that the law will not be always verified; for one chemical ingredient, by getting the start, may do damage, which the other may fail to retrieve. In this way the gold toning solution acts; that is, when it is used separately and prior to the use of the hyposulphite toning solution; for by its bleaching property the fine and thin shades, or mezzotints, as well as the delicate lines, points, and marks, are all more or less deteriorated, and the print, if kept in this toning solution until the blue or the violet tint has been arrived at—until, in fine, the gold has displaced the silver which originally formed the picture

\*The translation of this process will soon appear.

—will be very much impaired in vigour and brilliancy; in fact, it will be a feeble, a bleached picture. Now when this bleached picture is immersed in the so-called fixing solution, it is submitted to two actions—a toning action upon the parts which form shades and middle tints, and a solvent action upon the chloride of silver which has undergone no physical change from light. Neither of these actions has any power whatever to restore the parts that have been destroyed by the gold toning solution, nor do they add to the vigour of the print by increasing the contrasts, because the toning of the hyposulphite does not owe its efficacy to accretion or deposit. Hence it is that such a picture leaves the fixing solution as weak and bleached as when it was placed in the same; it has simply changed its tone and been fixed.

Have we any reason to allege that the action is different when the print is immersed at once in a mixture of the two toning solutions? Let us see.

Suppose it is immersed in the hyposulphite first, until it is toned to a chestnut hue, and fixed. It will be observed that, in this case, it has undergone no deterioration such as that which is produced by the gold toning solution; in fact, we shall be constrained to come to the conclusion that hyposulphite of soda tones and fixes without bleaching.

Secondly. We shall observe, furthermore, that all attempts to tone the print with the gold solution after it has been toned and fixed in the soda bath are futile; we can hence conclude that the latter solution must have some restraining action upon the gold solution when the two are mixed together. These, then, are the only theoretical reasons at present known, which ought to induce us to rely upon the mixture of the two toning solutions, as preferable to the application of the gold solution first, and hyposulphite afterwards. In practice, we find that the print is much less injured in the mixed toning solutions than when treated by the modern method of toning and fixing in separate baths. In the mixed bath the pictures are decidedly more brilliant, and every tone that can be composed of a chestnut hue and a blue-black by the varied admixture of the two solutions that produced them can be obtained in this mixed bath if the prints are allowed to remain in it the proper length of time. Our readers may be inclined to think that the prints must be in some degree injured if they are allowed to remain several hours in the hyposulphite solution. We have not found this to be the case, and our experience is derived from the toning and fixing of more than seven hundred stereographs during the last month. Some of the prints remained in the mixed solution over night, and were found the next morning as black as an engraving; if kept in still longer, the tone assumes a greenish tinge. But in all these cases there is no difficulty in removing every trace of hyposulphite from the prints by subsequent washing; and when this is effected, there ought to be no alarm about their keeping properly. With these preliminary remarks, we will now proceed, and describe our present toning and fixing process.

#### TONING AND FIXING SOLUTION.

Water	...	...	...	32 ounces
Hypsulphite of soda	...	...	...	8 "
Acetate of soda	...	...	...	4 drachms
Chloride of gold	...	...	...	15 grains.

Dissolve the gold previously in an ounce of water, and then add it to the stock solution. Keep the stock solution in an open bath all the time, and add to it fresh gold and hyposulphite when required. It is a good plan to dissolve fifteen grains of the gold salt in two ounces of water, and add a drachm of the solution to the bath each time or day just before you are going to tone. Throw into the solution also about half-an-ounce of hyposulphite of soda after each day's severe strain upon it. In this way it will work for a long time, care being taken to supply fresh water as it becomes exhausted by evaporation or convection with each print when removed from the bath. The solution, too, is always ready and in good working condition to receive the

prints direct from the pressure-frame, without any previous washing. In this way the bath is seldom overcrowded with prints at the same time, for, as one goes in, another, in general, is ready to be removed to the water-dish.

(To be continued.)

#### STUDIO HINTS.

BY A PRACTICAL MAN.

*Varnishing.*—As this practice will be most extensively adopted since Mr. Blanchard's method of preserving prints has been made known, all who wish to avoid vexation and trouble in regard to the brush should keep their varnish in a wide-mouthed caper bottle, the flat brush fixed through the cork; and as the varnish gets used and lower in the bottle the brush can be pushed further through the cork, to be always in the varnish.

A cheap and effective substitute for a *Glazing Press*, and admirably adapted for the new cabinet portraits, may be arranged as follows:—A roller of beech or birch, from one to two feet long, and of good proportionate thickness, must be accurately turned and polished. The print is to be placed on a sheet of plate glass, or the top of a smooth, hard, heavy table, or it may be placed between pressing-boards. The roller is then to be placed on the top, and worked backward and forward, mangle fashion, with a heavy lithographic stone. This will give a highly-glazed surface to prints at a small cost.

*Graduated Backgrounds* (cheap, effective, and can be made by any one).—Get six or eight feet of the 4-ft. 6-in. wide cartoon paper, or a very large sheet of brown packing-paper, some of which is made in very large sheets; damp it, and strain against a wall, or strain on a frame previously covered with thin calico; when completely dry and tight, mark a circle in the centre, or about where the sitter's head would be; then put some common lamplack in a saucer or plate, and work it round the centre circle that has been left for the head, taking it up with a cloth as wanted. This, with very little trouble, will give an admirably graduated background, either from a dark centre to light outside for grey, white, and light heads, or a light centre to dark outside for dark heads. If the brown paper centre is to, dark, bring it up with a rubbing of flake white. This only wants trying, to be universally adopted, as it is so simple and so easily done.

*Stippling the Glass of Studios*, so as to give a flat or ground appearance. This is best done with pure, good, bright and clear white lead, so mixed as to be what decorators would call stiff flatting. This should be dabbed or stippled on with the point of a new, good-sized sash-tool; an old worn-down brush is useless, and will only make dabs and smears. There is also another way of regulating the studio light; viz., by the use of thin blue gauze mediums, as used by panorama painters in producing some of their soft and graduated effects; the blue gauze used in theatres for making the dresses of fays and fairies is the article to be used. This can be arranged so as to cover any desired part of the top or side lights in one, two, or three thicknesses, and be the means of producing a variety of soft, artistic, and satisfactory effects.

*The Cabinet Background* will be found useful. It is formed by hanging three frames together; to fold, open out, or shut up like a large clothes-horse. This, judiciously used, will give great relief and roundness to the figure, as the light may be increased or diminished by merely splaying or contracting the frame on the side nearest the window; a frame must also be arranged to soften the top light. The frames forming the two sides and back must be skeleton-frames, to be covered with open leno or blue gauze, and, by their arrangement and modification, will produce a great variety of pleasing effects.

## Proceedings of Societies.

### NORTH LONDON PHOTOGRAPHIC ASSOCIATION.

THE usual Monthly Meeting was held on the evening of Wednesday, the 1st inst., in Myddelton Hall, Mr. W. W. KING in the chair.

The minutes of a former meeting having been read and confirmed,

Mr. E. DUNMORE read a paper on Some Art Aspects of Photography (see p. 19).

After a vote of thanks, it was resolved, as the meeting was small, to adjourn the discussion on the paper until the February meeting.

## Correspondence.

### CARBON PRINTING.

SIR,—After my season's work, which, I am happy to say, puts me out of the position of joining in the dolorous chorus which is being pretty generally sung by the profession of late (the more is the pity), I took a week's holiday to myself for the purpose of seeing what was doing away from home, determined to bag every wrinkle that could be turned to good account in future practice.

I have long desired to try my hand at carbon printing, but, I dare say, like many more, was deterred from doing so by the conflicting statements made regarding its practicability. So, when out for my week, I one day turned my steps towards Newcastle, and called on Mr. Swan, and, sir, if he were a stranger to you, I would tell you of the kind and gentlemanly manner in which I was received; my only letters of introduction being a few cartes, the backs telling where I did them, and the other side showing how. He kindly requested me to accompany him to the printing establishment, and there I saw the process gone through with pictures of every size, from cartes up to whole sheets, and in every variety of tone suitable to the subject, from pure black to a warm brown, all equal, so far as I could judge, to what silver prints would be from the same negatives, and as regards uniformity in depth of printing superior.

I was so thoroughly satisfied with what I saw that I resolved that my first work on my return home would be a trial at carbon printing, and the few cartes I enclose will give you an idea of my success. I find the working of it so simple and certain that I would have no hesitation in adopting it for all my work; and consider that Mr. Swan is justly entitled to substantial remuneration for the skill, painstaking perseverance, and time he must have expended in bringing the process to such perfection.

I noticed lately that Dr. Vogel suggested the use of the screw press for transferring—a good idea—but, I think, only suitable for the first transfer. Where quantities were done the screw press would be valuable, as the undeveloped prints could be neatly laid on the caoutchouc-coated paper (an uncut sheet, if the press was large enough), and piled into the press between sheet-brass or printers' pressing-boards, when one squeeze would do for hundreds of prints. The re-transfer requires a much sharper nip to ensure perfect adhesion, and for this a copper-plate or lithographic press is better adapted.

JOHN HENDERSON.

Perth, Jan. 6th, 1868.

[The prints which Mr. Henderson encloses are excellent. The question of screw pressure *versus* rolling pressure can only be decided by experience. Mr. Cherrill, who first proposed it, has succeeded very well with the screw press, and Dr. Vogel confirms his view. Our own predilection, theoretically, is in favour of rolling pressure, with which we have succeeded. As yet, however, we have not tried the screw pressure.—ED.]

## SUGAR IN THE PRINTING BATH.—INDIA-RUBBER MOUNTING.

DEAR SIR,—I beg to thank you and Mr. Bovey for the hint as to the use of sugar in the printing bath. I tried it some weeks ago, when you first mentioned the subject, and, as no formula was given, I added one drachm of sugar to each pint of a 40-grain silver bath. I have, within the last few days, obtained prints with perfectly pure whites, on paper which has been excited three weeks. I fancy that the paper is a little more sensitive after this treatment, but of this I cannot speak with certainty, as I have not tried a sample prepared with and without the sugar side by side.

I have been trying the india-rubber mounting, but without much success. I made a 20-grain solution in benzole. It took some days to dissolve properly, but appeared all right at last. I then mounted some cards, as I thought with success, and after rolling they looked very nice. To my disgust, however, when I looked at them some hours after, the heat of a warm room had made most of them curl up from the mount at the corners, and in some, half the prints were off. Is there any remedy for this?—I am, sir, gratefully yours,  
PROBATUS EST.

[The tendency in the print to leave the mount is a common result of using too thin a solution of india-rubber. A very attenuated layer is comparatively useless. In using glue or paste it is a maxim to apply the thinnest coating possible. 'A carpenter will tell you that the best joint is made with the smallest quantity of glue, and he will sometimes rub two surfaces together to press out all superfluous glue. But it is to be observed he uses the smallest quantity possible of glue of the *right thickness*, not glue made as thin as possible. It is possible to make glue and paste too thin to secure adhesion. But the conditions in using india-rubber are altogether different. It does not dry into a hard substance binding the two surfaces to which it adheres. It continues in the form of an elastic gum, a thin layer of which readily yields to a strain which is greater than its own elasticity. It is necessary, therefore, that the layer should be thick enough to resist any possible tension to which it may be subjected. A 20-grain solution ought to be strong enough, but it has probably been spread thin.—ED.]

## EXPLANATION.

SIR,—We shall be obliged if you will kindly allow us space in the News to declare that we have nothing to do with "A. B.," who in your last advertisement cheap printing, and refers to Mr. Seeley, of Ware.

We think that surely competition in *price* has reduced photography as profession too low already!

The effort should rather be to raise both price and quality.

A. AND E. SEELEY.

The Ferns, Richmond Hill, Jan. 8th, 1868.

## Talk in the Studio.

THE MEETING OF THE PHOTOGRAPHIC SOCIETY.—At the next meeting of the Society, to be held on Tuesday evening, in Conduit Street, Mr. J. Spiller, F.C.S., will read a paper, entitled, "Researches on the Hyposulphites and other Fixing Agents. Part I." We hope that a good attendance will be present to hear a paper on such an interesting subject.

GUN-COTTON AND NITRO-GLYCERINE.—Professor Doremus, at a recent inquest held in the United States on the bodies of several men killed by a nitro-glycerine explosion, stated that if gun-cotton be immersed in the proto-chloride of iron it turns into common cotton; the same experiment was tried with nitro-glycerine by mixing it with proto-chloride of iron, and it reverted into common glycerine. If gun-cotton or nitro-glycerine is not carefully washed to get rid of the acid, a gradual decomposition will ensue, producing gases which, if the vessel be closed, will explode. Nitro-glycerine carried

about exposed cannot explode, even if you drop a coal of fire into it; if the liquid is confined, or is under pressure, then an explosion will ensue. If gunpowder or the fulminates of mercury, silver, or gun-cotton be ignited in a vacuum by a galvanic battery, none of them will explode.

**PHOTOGRAPHY AND THE RAILWAY CARRIERS.**—A case of some interest to photographers in the transit of their productions has just occurred at Penzance. It appears when the Science and Art Department decided on allowing a series of their framed and glazed photographs to be sent to the West for exhibition, in connection with the schools of design at Penzance, the agent of the railway into whose hands they were placed for transit to their destination entered the cases containing the photographs, &c., as books. Now, to make the transaction better understood by the general reader, it should be stated that the railway companies have three scales of charges: books, £2 per ton; pictures, with glass, £4 per ton; and plate glass, £6 per ton. It appears that by a little sharp practice the person entered the pictures as "books," and got them conveyed at the rate of £2 per ton, and then charged those to whom they were directed for plate glass, at £6 per ton. Now the foreman of the Committee was sufficiently wise, though he did not come from the East, to know that this was a very exorbitant charge, and refused to pay it, when another account was handed to him somewhat lower; but this he deemed too much, went to the railway managers, had the whole affair opened up and inquired into. The case was then heard before the Penzance magistrates, who inflicted a penalty of twenty shillings on the agent, at the same time saying, that had the principals been before them in the case they would have imposed the full penalty of £10 and costs; so that photographers in sending their goods to exhibitions, &c., must be careful, and see that the cases are properly entered and properly described, as the Act of Parliament gives the railway companies great power in any case of wrong description and entry.

**DISHONESTY.**—Some weeks ago, we reported the committal of Walter Whitlow, for the theft of negatives, prints, &c., from his employer, Mr. Duffy, of Bath. At the recent session he was found guilty, and sentenced to six months' imprisonment with hard labour.

**PHOTOGRAPHS OF PAINTINGS.**—One of the most celebrated landscape painters of France, who has just died, M. Theodore Rousseau, has, by his will, instructed that all the works remaining in his possession are to be collected and photographed, and, if circumstances permit, they are to be published in a collected form, after the manner of the "Livre de Verité" of Claude Lorraine, or of the "Liber Studiorum" of Turner.

## To Correspondents.

**A SUBSCRIBER.**—There are various methods of making a plain paper print transparent. Either wax or varnish will answer; but if you require it to be attached to glass the use of a varnish will answer your purpose best. The print should first be soaked in hot water to remove the size as completely as possible. It may then be treated either with mastic varnish, or a varnish made by dissolving Canada balsam in turpentine. A strong spirit varnish might be used, but as it dries rapidly the manipulation is not so easy. The print should be saturated with varnish, and the glass surface coated with varnish, and the two brought together carefully so as to exclude air-bubbles.

**F. A. N.**—The best plan for such a side-light as yours is to have the curtains sliding on a rod with rings, the whole curtain for the side, triangular piece as well, being in one piece. A cord must run along the rod, being attached to each ring, running over a pulley at the highest end, and hanging down. By pulling this string the blind will slide along and up the rod; the cord by which it is pulled can then be tied to a hook so as to hold the blind in position, drawn just to such extent as may be required. 2. All the samples of aluminized paper you name are, we believe, good. We have, especially, heard Nos. 1, 2, and 5 praised; but we have not made comparative trials of each, and cannot speak absolutely from personal knowledge.

**AMATEUR.**—It is probable that the lens to which you refer, of the maker you name, will answer your purpose; No. 3 will be best for the size you require. For pure landscape, nothing will answer your purpose better than the first landscape lens you mention. Possessing these two lenses you are right in conjecturing that the triple will be comparatively unnecessary.

**A BEGINNER.**—The copyright of a photograph taken to order, and

for what the statute terms a "good and valuable consideration," does not vest in either the producer, or the person ordering, without an agreement in writing made at the time, stating to whom the copyright is to belong. The producer of any photograph ordered and paid for by another has no right to sell the prints without the consent of the person so ordering; but neither of them possesses a copyright without an agreement. The only case in which the copyright vests in the producer without any agreement is where he produces the photograph at his own charge and for his own purposes. The cost of registration is one shilling for the fee, and one penny for the "form" to be filled up. Personal attendance at the Registrar's Office is necessary. Our Publisher will superintend the proper entries, and pay the fee of a form properly filled up, if one shilling and three-pence in stamps be sent to him. A separate entry and separate fee is necessary for every view of any object. One entry and one fee only protects the picture in one negative, and any other negative with the slightest variation requires separate entry and fee.

**TWELFTH NIGHT.**—The negative you forward is not well adapted to the production of transparencies for the magic lantern. It is not dense enough and not clean enough; the lights are feeble and the shadows are fogged. For copying engravings for such a purpose you will find the use of an organico-iron developer well suited, as aiding in the production of clean shadows. Your exposure has been a little too long also, and it is probable that your collodion is new. Try adding a few drops of tincture of iodine to your collodion until it is a deep sherry colour. In copying an engraving be very careful to have it quite flat and the camera quite parallel with it. 2. The use of a background painted in natural colours instead of in monochrome would not impede manipulations, but would make results uncertain and often inharmonious, because of the varying photographic value of colour. 3. If judgment be used, natural objects may often be introduced as accessories in portraiture. We have seen, at times, very effective pictures produced by the introduction of natural foreground objects in front of a painted landscape background scene.

**G. WILLIS (Sensborough).**—As Mr. Swan's carbon process is protected by a patent, no one can, of course, work it without his licence. The possession of our work on carbon printing carries with it no right to practise the patent process, but will teach those possessing the licence to practise the process. The question of exclusive licences is one of a purely commercial character, and will doubtless be governed by commercial consideration.

**W. M.**—THE YEAR-BOOK OF PHOTOGRAPHY for 1868 was published on the 27th of December, and has not been out of print since. Any answer "not out" or "out of print" since that date has been given in error.

**AJAX.**—We do not know of any agent for the Leptographic Paper in London.

**F. A. OAKES.**—See answer above.

**R. N. D.**—You require a thicker solution of india-rubber. The 15-grain solution with a large residue which you describe is practically much weaker, probably not more than 10 grains to the ounce. 2. The thin foggy image which you describe may be due to the condition of the bath, or of the collodion, or of the developer. Probably you are using a new and somewhat thin collodion. Add a little more pyroxyline to the collodion, and a few drops of tincture of iodine. 3. In copying a map, use a portrait lens or a triple to secure freedom from distortion, and a moderately small stop. A view lens will curve the lines in the margin.

**R. D.**—The toning bath turning brown and ceasing to tone is most likely the result of contact with some trace of hyposulphite of soda. Possibly your fingers have been in contact with the fixing bath, and have then been immersed in the toning solution. This will produce the effect you describe. There is no remedy for it; you can only recover the gold by precipitation.

**TYRO.**—Collodio-chloride of silver properly prepared will keep in the dark a long time: how long we cannot say. The first sample we made was kept for twelve months before it became decomposed. We do not counsel, however, keeping it for more than a few weeks, as if free nitrate of silver be present, as it should be, it has a tendency to act upon the collodion, making the film rotten. The film leaving the paper is generally due to the use of a very tough collodion.

**PICKLE.**—The first of the recipes for joining glass to which you refer, if managed properly, will be found to answer. A thick solution of isinglass with a little powdered hydrate of lime made into a paste will make a good cement; or, quicklime and cheese made into a paste with a little water holds well.

**C. W. H.**—Regarding the subject of your strictures it is difficult to say anything here, except that there are many and varied tastes in existence. Thanks for your complimentary remarks on the YEAR-BOOK.

**To Correspondents.**—Communications from LACHLAN MACLACHLAN, A. E. SCALES, and others in our next. Several Correspondents in our next.

### SILVER SOAP AS A SENSITIVE AGENT.

NOTWITHSTANDING the experimental activity which often prevails in photography, it is singular how long a known sensitive agent will remain little examined and unutilized. The oleate of silver is one of these substances. About five years ago M. Quaglio called attention to its use in a method of photo-lithography, of which we have heard no more. M. Carey Lea, Dr. Liesegang, and others, gave some attention to it about the same time. Dr. Phipson, in his *Préparateur Photographique*, published four or five years ago, referring to this substance, states that it is extremely sensitive to light, blackening completely in an exposure of from five to seven minutes. He mentions that spread upon a piece of ground glass, and exposed under a negative, it yields a print of a fine black tint, which may be fixed by treatment with dilute hydrochloric acid, followed by hyposulphite of soda. Some time in the year 1866 we received a communication from an ingenious correspondent, Mr. R. Courtenay, some fine examples of instantaneous photography, accompanied by the information that the accelerating agent he employed in his collodion, which at once gave rapidity and vigour, was oleate of silver. We suggested at that time that this organic salt of silver would probably prove of service in the dry collodion processes, and, further, that in our collodio-chloride process, which would probably prove valuable in securing fine prints. We commenced some experiments with it for the latter purpose; which, from the intervention of other important engagements, were, however, never carried out. The simple experiment then made consisted in adding about three grains of Windsor toilet soap, finely scraped, to an ounce of collodio-chloride of silver, and, after a few hours, trying it for printing. The sensitiveness was enormously increased, and a considerable accession of vigour was secured. The results were full of promise; but, as we have said, the experiments were pushed aside by other matters at the time, and have not been renewed. We shall resume the experiments at an early opportunity.\*

M. Carey Lea, to whose activity and ability as an experimentalist photographers are already largely indebted, has recently made a new application of silver soap, which promises to prove of great value. He also uses it in a dry collodion process, but in an extremely simple and elegant manner. Taking the collodio-bromide process of Messrs. Sayce and Bolton, he forms in it oleate of silver to supply the sensitive organic salt which is found necessary or desirable in dry processes generally. The results are described as very encouraging, which, *a priori*, we are quite prepared to believe. The collodio-bromide process, under the management of Mr. Mawdsley, at the Liverpool Dry Plate Com-

pany, gives plates admirably stable and certain, with a degree of sensitiveness exceeding that of most dry plates, and it seems very probable that the addition of an agent like oleate of silver will still further increase their sensibility.

In his formula, which we published last week, Mr. Lea recommends the use of an official tincture of soap, chiefly on the ground that, being employed in pharmacy, it can be purchased ready for use, and that alcoholic solutions of soap are troublesome to prepare. As the tincture of soap to which he refers is an American preparation, the argument of facility in obtaining it is not available to the English reader, to whom, therefore, as the preparation of his own soap solution, or his own oleate of silver will be necessary, a few words on the subject may be useful.

Oleate of silver is a yellowish white substance somewhat resembling wax in texture; it is not soluble in water, but readily soluble in ether and alcohol, and therefore in collodion. It is formed by mixing six parts of nitrate of silver in concentrated solution with seven parts of Castile soap in strong solution. The oleic acid and margaric acid, which are united with a soda base, combine with the silver, and a precipitate, consisting chiefly of oleate of silver, with a little margarate of silver, is thrown down, leaving nitrate of soda in solution. The precipitate is washed, and pressed dry between folds of blotting-paper. It may be added to collodio-bromide or collodio-chloride of silver in this form, and will readily dissolve in the proportion required.

A still simpler plan of operation would consist in the preparation of an alcoholic solution of soap, to be used in the preparation of the collodion. Most of the alkaline oleates, stearates, and margarates, are in some degree soluble in alcohol, and will form a strong solution, if cut into shavings and digested for some time; or the soap might be added in fine shavings direct to the collodio-chloride or collodio-bromide, without much risk of inconvenience. As the soaps with a potash base are most soluble in alcohol, they should be chosen. Common soft soap, which is an oleate of potash, may with advantage be used for this purpose. Two or three grains of this oleate added to each ounce of collodio-bromide or collodio-chloride of silver when it is first prepared—having, of course, about an equal weight of free nitrate of silver present to combine with it—will, it is probable, give a sufficient proportion of oleate of silver, without leaving any troublesome residuc.

### HYPOSULPHITE OF AMMONIA FOR FIXING.

In Mr. Spiller's interesting paper on Fixing Agents, read before the Photographic Society on Tuesday evening, he mentions that on using a bath of hyposulphite of ammonia subsequent to the ordinary fixing of the print, he was

\* We have, since writing the above, repeated the experiment with similar results. We shall have more to say on the subject shortly.

enabled to eliminate all but a very minute trace of the silver always left in the whites of the print after fixing with hyposulphite of soda; and expresses a conviction that if the ammonia salt can be introduced cheaply into commerce it will prove a great boon to photographers.

Mr. Spiller proposes to prepare the hyposulphite of ammonia, by double decomposition, from hyposulphite of baryta and carbonate or sulphate of ammonia, the hyposulphite of baryta being formed by mixing, in nearly equal parts by weight, chloride of barium with hyposulphite of soda, in concentrated aqueous solutions. The product is a pure salt of hyposulphurous acid and barium: a sample before us, prepared by Mr. Spiller, is in very fine, minute, and beautifully lustrous crystals something like pyrogallie acid in appearance, and something of the saponaceous feeling of stearite to the touch. From its insolubility it is, however, useless to the photographer, and is chiefly interesting from its fitness for the use for which Mr. Spiller proposes it. The practical extent to which hyposulphite of ammonia will prove a perfect fixing agent can, of course, be only determined practically. Theoretically it should promise a solvent power much more complete than that of other hyposulphites from the behaviour of the base ammonia as well as the hypochlorous acid towards salts of silver.

Our object now, however, is to mention that in the spring of last year we received from an esteemed correspondent, Mr. F. H. Redin, Governor of Carlisle Gaol, and a skilful amateur photographer, some excellent prints which had been fixed with hyposulphite of ammonia. Tested with sulphide of ammonium the existence of silver in the whites appeared much less than is common; but still it was manifestly present. Mr. Spiller has used it as a second bath to eliminate, if possible, the silver from the whites of a fixed, albuminized print. If the use of a second bath be conducive to this end, notwithstanding the extra trouble, many a conscientious photographer will not hesitate to use it. When the old mixed toning and fixing bath was in vogue, Mr. Lake Price used to employ, and recommended in his useful book, a second bath of a strong, fresh solution of hyposulphite of soda to secure perfect fixation, applied when the print had acquired a proper colour in the first bath.

At the time we received the prints to which we have referred from Mr. Redin, he informed us that the hyposulphite of ammonia was prepared by a new process, by Mr. Lesh, one of the visiting justices of the gaol, and that he was prepared to introduce it into commerce. We hoped to have heard more of the matter, but it has not again come under our notice. Now is the time, however, to bring it under the attention of photographers in a commercial way.

There is another question of importance introduced in Mr. Spiller's paper. One sample of hyposulphite of soda he examined contained not less than sixteen per cent. of impurity. The impurity was not necessarily injurious to the photographs subjected to its action, but the fixing bath would be weaker in just the proportion in which the impurity was present. To all large consumers of hyposulphite of soda this suggests the importance of testing each stock when first purchased by the simple method indicated in the paper. To smaller consumers, or those unable or unwilling to undertake such tests, it suggests the importance of a liberal use of the fixing salt, so as always to be on the safe side. The use of excess of hypo is only a little waste of a cheap salt; the use of too little is risking the permanence of valuable pictures, and the waste of reputation.

#### ANOTHER SENSITIVE SALT FOR PHOTOGRAPHERS—FLUORIDE OF SILVER.

Whilst all the haloid salts of silver have been for years known as sensitive to light, the chloride, iodide, and bromide only have been available to photographers. The fluoride of silver, although extremely sensitive, possessed a peculiarity which disqualified it for the uses for which its congeners were

employed—it was soluble in water. The consequence was, that when a fluoride was employed in collodion by Archer and others, the fluoride of silver, formed in the film by double decomposition in the bath of nitrate of silver, being itself soluble, was dissolved by the aqueous solution, and lost from the film as fast as it was formed. The insolubility in water of iodide, bromide, and chloride of silver is the quality which has made them especially suitable for manipulative convenience, whilst the solubility in water of the fluoride has prevented its utilization in photography.

In the course of some recent experiments by M. Prat, another form of fluoride of silver has been discovered, which differs essentially from the soluble salt which has hitherto been known by chemists. The new salt is stated to be more sensitive to light than chloride of silver, and, being insoluble in water, it is available for the operations of the photographer in the same degree as the other haloid salts.

M. Prat's paper, *Fluorine and its Compounds*, was recently communicated to the French Academy, but will not be published at length until the chemical referees of the Academy have reported thereon. Our excellent contemporary, the *Chemical News*, has, however, a full abstract of the paper, which, as it will possess much interest for many of our readers, we subjoin:—

"M. Prat considers that chemists have hitherto been mistaken as to the composition of fluorides and the theory of fluorine. He regards the fluorides as in reality oxyfluorides, and the equivalent of fluorine as consequently much higher than is usually supposed. He represents fluoride of calcium by—

2 equivalents of calcium	...	...	40.0
1 equivalent of oxygen...	...	...	8.0
1 " the new fluorine	...	...	29.6
			<hr/> 77.6

This accords with the known analysis of fluor spar, since it contains 51.5 per cent. of calcium.

"By doubling the old equivalent of fluorine (19), we get 38; that is to say, nearly the sum of the equivalents of oxygen (8), and of the new fluorine (29.6) = 37.6.

"According to M. Prat, in order to obtain true fluorine, it suffices to heat fluoride of calcium with chlorate, or, rather, with perchlorate of potash, since it is only after the formation of this latter salt that the reaction takes place. Oxygen is disengaged, and also a product which silver absorbs. The compound so formed is fluoride of silver, insoluble in water, soluble in ammonia, from which it is precipitated by nitric acid, and more rapidly altered in the light than chloride of silver. Neither chlorine nor oxygen attack it even at the fusing point of the fluoride. It is, however, decomposed by potash at a dull red heat, and this reaction permits its analysis; it contains—

Silver	...	...	0.785	...	...	108.0	= 1 equivalent
Fluorine	...	...	0.215	...	...	29.6	" "
Fluoride of silver	1.000					137.6	

"This fluoride of silver, insoluble and very stable, and having great analogy with the chloride and the other compounds of this family, differs essentially from the soluble fluoride of silver of chemists, which, according to M. Prat, is a compound of—

"Fluorine combines with chlorine. To obtain this compound it is sufficient to pour a weak solution of the hydrofluoric acid of the chemists into a solution of hypochlorous acid: there form

"Fluoride of chlorine is gaseous, of a more intense colour than chlorine. It converts silver into a mixture of chloride and fluoride.

"Fluorine may be isolated, according to M. Prat, by heating fluoride of lead of chemists (1 part) either with nitre (5 parts) or with binocide of manganese (2 parts): oxygen and fluorine are evolved. A platinum alembic must be used. The oxygen is removed from the mixture by passing over fragments of heated baryta.

"Fluorine is gaseous, almost colourless, of a chlorous odour, visibly fuming in the air, incombustible, and heavier than air. It bleaches indigo, and reddens and bleaches litmus. Ammonia produces fumes with fluorine, and will thus detect traces of it. It immediately decomposes water at the ordinary temperature. It combines with hydrogen in diffused light. Fluorine decomposes hydrochloric acid gas, and eliminates bromine and iodine from their compounds. It unites with boron and silicium, and with all metals of the first five groups."

## THE USE OF CLOUDS IN LANDSCAPES.

BY LUX GRAPHICUS.

The subject of printing skies and cloud effects from separate negatives having been again revived by the reading of papers on that subject at the South London Photographic Society, I think it will not be out of place now to call attention to some points that have not been commented upon—or, at any rate, very imperfectly—by either the readers of the papers or by the speakers at the meetings, when the subject was under discussion.

The introduction of clouds in a landscape by an artist is not so much to fill up the blank space above the object represented on the lower part of the canvas or paper as to assist in the composition of the picture, both as regards linear and aerial perspective, and in the arrangement of light and shade, so as to secure a just balance and harmony of the whole, according to artistic principles.

Clouds are sometimes employed to repeat certain lines in the landscape composition, so as to increase their strength and beauty, and to unite the terrestrial part of the picture with the celestial. At other times they are used to balance a composition, both in form and effect, to prevent the picture being divided into two distinct and diagonal portions, as evidenced in many of the pictures by Cuypp; on other occasions they are introduced solely for chiaroscuro effects, so as to enable the artist to place masses of dark upon light, and *vice versa*. Of that use I think the works of Turner will afford the most familiar and beautiful examples.

In the instances cited, I make no allusion to the employment of clouds as repeaters of colour, but merely confine my remarks to their use in assisting to carry out form and effect, either in linear composition or in the arrangement of light and shade in simple monochrome, as evidenced in the engraved translations of the works of Rembrandt, Turner, Birket Foster, and others, the study of those works being most applicable to the practice of photography, and, therefore, offering the most valuable hints to both amateur and professional photographers in the management of their skies.

Before pursuing this part of my subject further, it may be as well, perhaps, to state my general opinions of the effects of so-called "natural skies," obtained by one exposure and one printing. Admitting that they are a vast improvement on the white-sky style of the early ages of photography, they fall far short of what they should be in artistic effect and arrangement. In nearly all the "natural skies" that I have seen, their office appears to be no other than to use up the white paper above the terrestrial portion of the picture. The masses of clouds, if there, seem always in the wrong place, and never made use of for breadth of chiaroscuro.

No better illustrations of this can be adduced than those large photographs of Swiss and Alpine scenery by Braun of Dornach, which nearly all contain "natural clouds;" but, on looking them over, it will be seen that few (if any) really exhibit that artistic use of clouds in the composition of the

pictures which evidence artistic knowledge. The clouds are taken just as they happen to be, without reference to their employment to enhance the effects of any of the objects in the lower portion of the view, or as aids to the composition and general effect. For the most part, the clouds are small and spotty, ill assorting with the grandeur of the landscapes, and never assisting the chiaroscuro in an artistic sense. The most noticeable example of the latter defect may be seen in the picture entitled "Le Mont Pilate," wherein a bald and almost white mountain is placed against a light sky, much to the injury of its form, effect, and grandeur; indeed, the mountain is barely saved from being lost in the sky, although it is the principal object in the picture. Had an artist attempted to paint such a subject, he would have relieved such a large mass of light against a dark cloud. An example of a different character is observable in another photograph, wherein a dark conical mount would have been much more artistically rendered had it been placed against a large mass of light clouds. There are two or three fleecy white clouds about the summit of the mountain, but, as far as pictorial effect goes, they would have been better away, for the mind is left in doubt whether they are really clouds, or the sulphurous puffs that float about the crater of a slumbering volcano. That photographs possessing all the effects required by the rules of art are difficult, and almost impossible to obtain at one exposure in the camera, I readily allow. I know full well that a man might wait for days and weeks before the clouds would arrange themselves so as to relieve his principal object most advantageously; and, even if the desirable effects of light and shade were obtained, the chances are that the forms would not harmonize with the leading lines of the landscape.

This being the case, then, it must be self-evident that the best mode of procedure will be to *print in skies* from separate negatives, either taken from nature or from drawings made for the purpose by an artist that thoroughly understands art in all its principles. By these means, especially the latter, skies may be introduced into the photographic picture that will not only be adapted to each individual scene, but will, in every instance where they are employed, increase the artistic merit and value of the composition. But to return to the subject chiefly under consideration.

Clouds in landscape pictures, like "man in his time," play many parts—"they have their exits and their entrances." And it is almost impossible to say enough in a short paper on a subject so important to all landscape photographers. I will, however, as briefly and lucidly as I can, endeavour to point out the chief uses of clouds in landscapes. Referring to their use for effects in light and shade, I wrote, at the commencement of this paper, that the engraved translations of Turner afford the most familiar and beautiful examples, which they undoubtedly do. But when I consider that Turner's skies are nearly all sunsets, the study of them will not be so readily turned to practical account by the photographer as the works of others,—Birket Foster, for instance. His works are almost equal to Turner's in light and shade; he has been largely employed in the illustration of books, and five shillings will procure more of his beautiful examples of sky effects than a guinea will of Turner's. Take, for example, Sampson Low and Son's five shilling edition of Bloomfield's "Farmer's Boy," or Gray's "Elegy in a Churchyard," profusely illustrated almost entirely by Birket Foster; and in them will be seen such a varied and marvellous collection of beautiful sky effects as seem almost impossible to be the work of one man, and all of them profitable studies for both artist and photographer in the varied uses made of clouds in landscapes. In those works it will be observed that where the lower part of the picture is rich in variety of subject the sky is either quiet or void of form, partaking of one tint only slightly broken up. Where the terrestrial part of the composition is tame, flat, and destitute of beautiful objects, the sky is full of beauty and grandeur, rich in form and masses of light and shade, and generally shedding a light on the insignificant object below, so as to invest it with

interest in the picture, and connect it with the story being told.

From both of these examples the photographer may obtain a suggestion, and slightly tint the sky of his picture, rich in objects of interest, so as to resemble the tint produced by the "ruled lines" representing a clear blue sky in an engraving. Hitherto that kind of tinting has generally been overdone, giving it more the appearance of a heavy fog lifting than a calm blue sky. The darkest part of the tint should just be a little lower than the highest light on the principal object. This tint may either be obtained in the negative itself at the time of exposure, or produced by "masking" during the process of printing. On the other hand, when the subject has little to recommend it in itself it may be greatly increased in pictorial power and interest by a judicious introduction of beautiful cloud effects, either obtained from nature, or furnished by the skill of an artist. If the aid of an artist be resorted to, I would not recommend painting on the negative, but let the artist be furnished with a plain white-sky print; let him wash in a sky, in sepia or india ink, that will most harmonise, both in form and effect, with the subject represented, take a negative from that sky alone, and put it into each of the pictures by double printing. This may seem a great deal of trouble and expense, and not appear to the minds of some as altogether legitimate, but I strenuously maintain that any means employed to increase the artistic merit and value of a photograph is strictly legitimate; and that wherever and however art can be resorted to, without doing violence to the truthfulness of nature, the status of our art-science will be elevated, and its professional disciples will cease to be the scorn of men who take pleasure in deriding the, sometimes—may I say too often?—lame and inartistic productions of the camera.

## THE MAGIC LANTERN AND PHOTOGRAPHY.

BY JAMES MARTIN.

No. 4.

The pigments or colours to be used in painting upon glass must necessarily be more or less transparent, and therefore must be chosen principally for that property; nevertheless, there are some exceptions for special purposes, which require those that are opaque. In the general practice of painting, other qualities are also required; but, as such are not needed for our present purpose, I shall only point to those most suitable for it. The water colours most generally used by glass painters are, for yellows—gamboge, Italian pink, gallstone, and Indian yellow; as reds—carmine, madder lake, and madder carmine; as blues—Prussian blue, Chinese blue, and Antwerp blue; as orange—burnt sienna; as browns—madder brown, Vandyke brown, and copper brown; as black—lamp black. And the same for oil colours, except that ivory black is used in place of lamp black.

As I may suppose that my readers will not be having their colours constantly in use, I think it necessary to warn them, that some colours when ground as oil colours, such as carmine, the lakes, and Italian pink, have the peculiar property, after being kept some time, of becoming viscid, or what is termed fat, so that it is impossible to use them; therefore these and Prussian blue, also Chinese and Antwerp blue, should be purchased in powder, and stored in the small bottles before mentioned, a little being taken out at a time as wanted, and ground well into a stiff paste, with a very little nut oil, upon the glass slab, with the muller or palette knife, and then moved to the pieces of glass before named, each having its separate piece, or, at any rate, placed quite apart from each other: they must be kept free from dust. The slab and muller must be well cleaned after grinding each colour upon it. This is imperative for this reason, the brilliancy of tints depends upon the brightness and purity of the colours used to produce them. For example, gamboge and carmine mixed produce a splendid orange; carmine and prussian blue a magnificent purple. Mix the two

together, and a neutral colour is produced; again add some brown, and you have a dirty smudge of no colour (properly speaking). Cleanliness, simplicity, and decision are the best qualities for a beginner to aim at; softness and tone will be afterwards acquired as the eye becomes more educated. Perhaps these remarks may be considered somewhat beyond what is necessary for the mere painting of a lantern slide, but not so if the student intends to become excellent. I have seen slides that few landscape painters could have equalled upon canvas, and he who painted them must have possessed the education and feeling of a talented artist. In commencing the painting of a picture, the first thing necessary is the design or outline. If a photographic transparency is undertaken, this is, of course, already done as well as the markings of the shadow; but if a copy of any sort of picture in which (such as a line engraving or wood-cut) the shading would be inadmissible, in that case a photographic transparency can be taken, reduced to the size required, laid upon a piece of white paper under the glass to be painted upon, on which an outline must be traced with a fine camel-hair or sable pencil, taking great care to keep the two glasses exactly in the same relative position until it is finished. It is a very good plan to fasten them together by a piece of paper at the edges, which will insure their remaining in the same position. Having secured a true outline of the objects in the foreground and middle distance, a great deal of the outline of the extreme distance may be omitted, marking only the extreme contours and most prominent objects. The outline is to be made with lampblack water colour, used in such a body as to give a black line wherever the brush is drawn upon the glass. When the work is dry, proceed to pare down with the point of the penknife any gouty or uneven lines, using the straight-edge, T square, and bevel, also retouching them with colour as required. Do not be in too great a hurry to remove the under picture, as it is difficult to replace it exactly as it was at first; but carefully persevere in getting a clean and firm outline—which will repay all your trouble—as, without that, paint it how you may, it will never prove satisfactory. The outline is, in fact, the plan of the picture; by it you distinguish the tree from the shrub, the tall man from the boy, an ape from a man.

## ON NATURAL CLOUDS IN LANDSCAPE PHOTOGRAPHY.

BY J. R. JOHNSON.\*

At our last meeting, on the occasion of Mr. Howard's paper on clouds being read, I took the liberty of observing that although the production of artificial clouds by means of a second negative, taken at a different time from that at which the view was obtained, was an undoubted improvement to the photograph in place of the hard, white sky which it would otherwise possess, yet that the process must be considered a mere artifice or "dodge," and an imperfect substitute for the real clouds, or "atmosphere" of the landscape. I further stated that we possessed means by which the natural clouds, or, rather, the actual condition of the sky and "atmosphere," could be obtained with perfect accuracy; and I proposed, at the next meeting of the Society, to bring forward photographs to prove my allegation. I have come prepared this evening to fulfil my promise.

Upon the table will be found about forty photographs, by M. Braun, of Dornach, the eminent French photographer. They are all from single negatives, and are taken by the wet collodion process, by the Pantascopic camera, upon plates twenty inches by nine. The angle of view embraced is about 125°, or more than one-third of the whole circle of the horizon. I will, however, say nothing of the extent of view, nothing of the general excellence of these pho-

\* Read at a meeting of the South London Photographic Society, Jan. 9, 1868.

tographs, but will merely call attention to one of their qualities, viz., that quality which artists call "atmosphere," by which I understand the more or less truthful rendering, not merely of the more obvious atmospheric effects, such as cloud, fog, or sky, &c., but also that more delicate gradation of tints by which the amount of air or space lying between the observer and the more distant objects is indicated, and which, to a certain extent, is an element in the process by which the mind determines the distance of those objects. In this quality these views are unrivalled, I believe I may say unequaled.

They have another merit which will, I am sure, be appreciated by all professional photographers, and that is, that they have proved themselves to be most excellent photographs in a commercial sense. They have been sold by the producer at a very high price; yet in this country alone, I am informed, that the public has purchased them to the amount of nearly £4,000, that value being estimated at the wholesale price. Such a fact furnishes, I think, a fair argument in favour of excellence, and to the prejudice of the "cheap and nasty" style of photography, even when the English "Philistine" public is the arbiter of taste.

While these photographs are before us I am anxious to lay down for our discussion this evening two propositions:—1. I would assert that our photographic processes are capable of rendering, with perfect fidelity, and in all their detail, the natural atmospheric effects of a landscape. 2. That without such real atmosphere the view produced must be imperfect and untrue, whether regarded as an artistic study of nature, or as a mere picture.

If these propositions be established, on a future occasion I will endeavour to prove that this truthful rendering of nature—that is, the production of cloud and sky—and the perfect gradation of the landscape when no cloud is present, may be obtained at all times, and by all cameras, as well as by the Pantascopic camera, provided that proper means for regulating the exposure be adopted.

With regard to the first proposition, I apprehend that I have only to assure the gentlemen present that all the views shown are from single negatives to prove its truth. The views with clouds speak for themselves at the first glance; those where there is an even tint in the sky have only to be examined with a little attention to show that they also possess in a remarkable degree the same quality. Look, for instance, at the views of the Valley of Chamounix, in which no cloud is seen. See the extraordinary delicacy of gradation of each successive peak. The foreground of many of these views is fully defined, and of a mere grey tint, and the sky and distant mountains are not white; yet what an infinity of tones there are between these two extremes! Look up the centre of the valley and observe the beautiful haze which veils, yet does not conceal, the distance. Had these views been taken in the ordinary way—that is, by giving equal exposure to the foreground and to the distant horizon—the great mass of detail in the extreme distance must necessarily have disappeared with such a light as must have been present when these views were taken; for, if the results before you have been produced by giving twenty times as much exposure to the foreground as to that distance, how could an equal exposure to each have succeeded?

With respect to the second proposition, it is, I think, almost equally self-evident with these views under examination. Take the lake scenes. Imagine that the beautiful skies are removed, and replaced by a hard, white surface, while the reflections of those skies in the water remain, as they might possibly do, presenting less intensity of actinic power than the objects themselves; and what would be the result, whether we look upon our view as a study of nature, or as a mere pleasing picture? I need not reply.

Now, what is true of these lake scenes is true, more or less, of all views in which the sky is lost, and has to be added artificially. It is not only in lake or river scenes that the influence of sky and cloud is witnessed; it is in all views. Look at any landscape extended before you, and

note its varying aspect as the sky above changes. How often we see, when wind exists, the shadows coursing each other over the landscape. This is, of course, an extreme case; but there is no view of which the "lighting" does not vary infinitely; and what is the "lighting" but the greater or less interception of the source of light by cloud? In whatever "lighting" we take our picture, then, the sky should accompany it, or we have not all the conditions present which nature presented to us when the view was taken, and of which the peculiar aspect of that view is the consequence.

I will not further trespass upon your time by any additional observations, but will leave the views to speak for themselves, believing that they constitute the most powerful argument which can be urged in favour of natural, over artificial clouds.

## RESEARCHES ON THE HYPOSULPHITES AND OTHER FIXING AGENTS.

### PART I.

BY JOHN SPILLER, F.C.S.\*

NEXT in importance to the discoveries of Daguerre and Fox Talbot may unquestionably be ranked the introduction of hyposulphite of soda as a fixing agent by Sir John Herschel; and so long as photographers were limited to the use of plain papers, or those sized with gelatine only, there was never any difficulty experienced in the complete removal of the silver from the white (unaffected) portions of the paper composing the ordinary photographic print. At a later date, when albuminous coatings came to be applied to the surface of the paper for the purpose of improving the sensitiveness, and giving greater brilliancy and vigour to the resulting print, the few practical difficulties which presented themselves at the outset were believed to be susceptible of being readily overcome. I refer particularly to the tardiness with which the operations of toning, fixing, and washing the prints had to be conducted in consequence of the repellent character of the sensitive surfaces of paper so prepared; and a grand improvement in the subsequent history of albuminized paper was the separation of the fixing and toning processes. Before this practice was adopted prints with "pure whites" (as they were termed) were rarely met with, for the protected portions of the paper were almost invariably tinged with yellow, and the darker shades in the print had usually a bistre or greenish tone. These effects were shown, by Mr. Hardwich and others, to be due to the "sulphuration" of silver in the print as a consequence of the liberation of sulphur from solutions compounded of hyposulphite of soda and terchloride of gold. The normal reaction of these *sel d'or* baths was acid—a condition which proved unfavourable to the permanence of the fixing-salt—and entire success was supposed to be guaranteed when an alkaline gold-toning bath was employed, followed by immersion of the prints in plain hyposulphite.

Whilst these difficulties were being gradually surmounted, a hint was thrown out by MM. Davanne and Girard to the effect that the so-called "pure whites" of the albumen print still retained a small proportion of silver in an insoluble condition, and most probably in the form of sulphide. No notice appears to have been taken at the time of this important announcement, and the eminent French investigators did not seem to appreciate the necessity of addressing themselves to the discovery of a remedy.

At a later period, October, 1862, I was led to an independent observation of the same fact, and at once applied myself to an investigation of the circumstances attending the formation of this silver compound, and the possible means of removal. My experiments went to prove that the metal was retained in the whites of the albumen print, and, indeed, in all parts of the coating, in the form of an argentic-organic compound, colourless, inalterable by light, and

\* Read before the London Photographic Society, Tuesday, January 14th

comparatively insoluble in hyposulphites and other fixing agents. It could not be a simple sulphide, for the test by which I discovered its existence in the paper was the production of a brown stain upon moistening the white surface with sulphide of ammonium. It is not my intention to recapitulate the numerous trials I made with a great variety of chemical solvents in the hope of removing the whole of the silver locked up in this form of organic combination; I will merely state that these results were recorded in the PHOTOGRAPHIC NEWS at the time, and that, as the practical result, I recommended the addition of carbonate of ammonia to the ordinary hyposulphite fixing bath, with the view of securing the twofold object of preventing, by its alkalinity, any chemical change or decomposition of the double hyposulphite; and, secondly, of directly aiding, by its special solvent properties, in the removal of this organic compound of silver. Since I had the honour of making this proposal, the advantage of adding carbonate of ammonia to the fixing bath has been practically tested and pretty widely endorsed. It is only by availing ourselves of *all* the resources at command that we can venture to look for a protracted existence of the rich and lustrous photographs upon albuminized surfaces; for, with silver in the whites, the print must be open to the attack of sulphuretted hydrogen gas diffused in the atmosphere, in addition to being liable to alteration by sulphuretted bodies arising from the incipient decomposition of albumen, gelatine, &c. employed in the preparation of the paper, or used for mounting the print.

The use of sulpho-cyanide of ammonium was found to be unsatisfactory when employed alone as a fixing agent, but since I received the assurance of a manufacturer that this salt could be produced at a cheap rate in the event of a great demand arising, I determined to test the efficacy of an addition of the sulphocyanide to an ordinary hyposulphite fixing bath. Since I have had these experiments in hand I notice that M. Obenetter\* has recently proposed the use of a combination of ten parts of sulphocyanide of ammonium with one part of hyposulphite of soda as a fixing agent applicable to the new description of collodio-chloride paper prepared by him. The proportions I have used differ widely from these,—my object being to supplement the action of the cheaper salt (hyposulphite),—and I, therefore, adopted the proportions already laid down for the use of carbonate of ammonia, viz., 4 : 1 in ounces respectively, and dissolved these salts together in a pint of water. As the result, I remarked that, from the presence of a trace of sulphide in the sample of sulphocyanide of ammonium employed, the protected parts of the print were not so purely white as usual; but I regret to say that the amount of silver in these portions did not appear to have been sensibly diminished. Mr. Wharton Simpson, Mr. Cherrill, and others, affirm that the use of this salt in the preparation of a toning bath is successful, so that its economic production on a large scale is likely to have an interest for photographers as well as for chemists.

Referring to the use of cyanide of potassium for reducing over-printed proofs, and for removing silver from the whites, Mr. Francis Eliot, in the YEAR-BOOK OF PHOTOGRAPHY, just published, suggests a renewed trial of this salt in aqueous solution, mixed with one-fourth or one-eighth proportion of methylated spirit. Used in this way he considers that it may be safely employed, particularly for the first-named purpose. This opinion coincides with my own experience, and I find that the addition of alcohol induces a more rapid and thorough penetration of albuminized papers subjected to its action; but it must be admitted that if a gold-toned print be thus treated its brilliancy, and colour will become somewhat impoverished. I have not, however yet tried its action upon prints at an earlier stage, as when simply washed from the excess of nitrate of silver. Upon the score of permanence it is much to be regretted that the cyanide cannot be employed for dissolving out the organic compound

of silver, for although it does this most effectually, it seems impossible to prevent a flatness and general want of vigour manifesting itself in prints so treated.

In the course of these experiments I deemed it desirable to test the hyposulphite of soda employed, for the several impurities likely to occur in it from its mode of manufacture. These are particularly carbonates, sulphates, sulphides, and chlorides. For the detection of the first I assume that the use of red litmus paper would prove sufficient; and a small quantity of this kind of impurity, if present, would do no harm. The samples tested by me did not contain any carbonate. The readiest test for the presence of alkaline sulphide is probably the immersion of a bright silver coin in the filtered aqueous solution. This I find by direct synthetical experiments to be a very delicate test, and more readily available than the addition of acetate of lead in small quantity to produce the brown sulphide of that metal. Although the sulphate of lead is nearly insoluble in water, and is usually precipitated on mixing any soluble sulphate with the acetate or nitrate of lead, I notice that this test altogether fails in detecting sulphate of soda in the presence of a fair proportion of hyposulphite. Neither is the detection of this impurity by chloride of barium so simple a matter as we should have expected. The facts are: Firstly, that hyposulphite of soda greatly interferes with the precipitation of sulphate of baryta, and only when the degree of impurity is considerable will there be formed any precipitate, even on standing; secondly, this test fails on account of the gradual production of a crystalline precipitate of hyposulphite of baryta, which would, of course, mask any indication of the sulphate occurring in admixture with it, unless by attending closely to intervals of time or degree of dilution, which would not be possible in practice.\*

For the detection of sulphate of soda, it is best to break up the constitution of the hyposulphite by adding a mineral acid. I find the following process answers well, and may be employed quantitatively:—Weigh out 100 grains of the sample of hyposulphite, dissolve in about 5 ounces of hot distilled water, raise the temperature to ebullition, and add half-an-ounce of pure concentrated hydrochloric acid; boil for five minutes to expel the sulphurous acid and agglutinate the sulphur, filter the solution, which will contain all the sulphate originally present in the sample, and add now chloride of barium to estimate its amount. In carrying out this process upon four samples of commercial hyposulphite of soda, one proved to be perfectly pure; two contained only a trifling amount, not exceeding 1 per cent., of sulphate of soda; and the last sample gave 16 per cent. of impurity from admixture of Glauber salt.

Chloride of sodium was not detected in any of these samples in quantity exceeding 1 per cent. A similar mode of examination was followed, using, however, dilute nitric acid to break up the hyposulphite, and nitrate of silver to precipitate any chloride.

It will be important to notice the fact, that in using a sample of hyposulphite containing altogether 17 per cent. of inert matter in the shape of sulphate and chloride of sodium, an additional one-fifth proportion of the fixing salt should be employed to ensure a successful result. This done, the simultaneous occurrence of these impurities would not be deemed prejudicial.

I have already alluded to a crystalline precipitate which slowly forms upon mixing in equal weights chloride of barium and hyposulphite of soda, both in aqueous solution. I have ascertained that this product is not a double salt, but the pure hyposulphite of baryta, in beautiful pearly crystals of small dimensions, heavier than, but somewhat resembling, pyrogallie acid. This body is interesting, from the circumstance that it enables us to prepare the ammonium-salt of hyposulphurous acid by double decomposition, with either

\* The precipitation of the chromate of lead is not altogether prevented by the presence of a soluble hyposulphite, but the chemical reaction is so far modified that a brick red precipitate, instead of the ordinary chrome yellow, makes its appearance.

the carbonate or sulphate of ammonia. From theoretical considerations, this should, of all the alkaline hyposulphites, prove to be the best fixing salt, since it unites within itself the two conditions I adverted to when speaking of the addition of carbonate of ammonia to the ordinary fixing bath; and from my limited experience of the hyposulphite of ammonia, made in small quantity and by the above indirect processes, I consider that its advantages in use, if substantiated by further investigation, would justify the manufacturer turning his attention to the substitution of ammonia for soda in preparing a commercial article. The facility of crystallization, permanence, and other properties of the new salt will have to be determined, and if it can be introduced cheaply into commerce, it is likely to prove a great boon to photographers. Using a bath of hyposulphite of ammonia subsequently to the ordinary fixing solution, I have succeeded in removing all but the last traces of silver from the white portions of albumen prints without injuring the brilliancy of tone for which these photographs are distinguished. I must, however, leave to a future occasion a fuller account of my experiments in this direction.

Woolwich, Jan. 10th, 1868.

### RESUSCITATION OF THE OLD TONING AND FIXING SOLUTION, AND THE TREATMENT OF THIS SOLUTION WHEN EXHAUSTED OR SATURATED.

BY PROFESSOR JOHN TOWLER, M.D.\*

#### WASHING THE PRINTS.

This is always an important operation, and must be thorough. We need not dwell upon this part; all know how to wash their prints, and have their own way and notions of doing the work: do it thoroughly. Finally, wash or soak them in a solution of common salt, which removes the last traces of the hyposulphite of soda; wash them again in fresh water, and then dry them. So prepared, the silver picture is more brilliant and vigorous than when toned according to our more modern plan; it remains to be seen whether it is equally permanent. Numerous yellow prints toned in this manner some years ago attest to the contrary; but we believe that in those days the same care in washing was not observed as is now observed; for several prints before us, that were toned in the mixed bath then, are still as fresh and white in the whites as the best prints now when taken from the wash-tub. If the fact of permanency can be proved to be a fact, we have no hesitation then in pronouncing the mixed toning and fixing bath as the easiest, the most economical, and the most reasonable of all existing toning and fixing methods.

#### DISPOSITION OF THE EXHAUSTED SOLUTION.

We do not yet know any certain criterion or test by which the solution can be easily shown to be saturated with chloride of silver; our plan is to reject the bath the moment it begins to precipitate a deposit; this takes place after it has been in continual operation for about three or four days; that is, after four or five hundred card-pictures have been toned in about a quart of it. Even at this stage it will continue to tone and fix; but it is somewhat doubtful whether it is advisable to trust it much further. The question, then, arises, What shall we do with the solution now?

There are several modes of treating it in order to extract the silver from it.

*First method.*—Throw into the solution a quantity of granulated zinc; that is, zinc which, when melted, has been poured from a height of three or four feet into a pail of water. By this process the zinc is broken up into small, irregular lumps, suitable for this purpose. Leave the metal in for several days, and stir the solution several times during this interim. The zinc in this operation takes place both of the silver and gold in the solution, and precipitates them—

the former as a fine silver-gray powder, and the latter as a black and a red powder. When the convenient time comes, pour the solution from the metals; add water to the latter, and wash the remaining pieces of zinc well, and then remove them back again to the same solution as before, in order to see that all of the noble metals have been removed. Wash the mixed powder first in dilute sulphuric acid, and afterwards in several changes of water, and then dry it. Place the dry mass or powder in a clean iron ladle, and heat it in an open fire-place to a low redness, and maintain it at this temperature. In this way any salt of silver, such as the sulphide, sulphate, &c., will be reduced to the state of oxide. Boil the powder which has been thus treated in about its weight of nitric acid, diluted with an equal quantity of water, until all is dissolved excepting a small portion of a reddish coloured powder; this remaining powder is gold, which may be dissolved in a mixture of two parts of hydrochloric and one of nitric acid. The former solution is next evaporated to dryness in a porcelain or glass dish; the dry salt is nitrate of silver.

We sometimes avoid the trouble of oxidizing the silver salts, and boil the gray mass at once in nitric acid; but in this way there is some loss.

*Second method.*—Filter the old bath and employ it for galvanic plating; it is in its present form in an excellent condition for coating copper and brass instruments with pure silver, either with or without the aid of the galvanic battery. It is very possible that you may find a market for this residual substance the moment it is known to be available for the purpose just indicated.

*Third method.*—Add a quantity of sulphide of potassium (liver of sulphur) to the old bath solution; the silver in this way is precipitated as sulphide, which may be sold as such to the refiner.

N.B.—The silver, which has been precipitated both from the old hyposulphite bath and from moist chloride of silver, is sometimes in a very curious condition—its allotropic condition, perhaps. This condition is shown by its difficult solubility in nitric acid. In consequence of this, we prefer mixing the dry metallic powder with its weight of carbonate of soda, and then fusing it in a Hessian crucible. The button of metal thus produced is now in a very soluble condition when submitted to the action of nitric acid—the gold remains undissolved as a black powder, and may, after separation from the fluid nitrate of silver, be washed first, and then dissolved in nitro-hydrochloric acid.

## Proceedings of Societies.

### SOUTH LONDON PHOTOGRAPHIC SOCIETY.

The usual Monthly Meeting was held in the City of London College on the evening of Thursday, January 9th, Mr. SEBASTIAN DAVIS in the chair.

After the minutes of a previous meeting had been read and confirmed,

Mr. J. R. JOHNSON read a paper on Securing Clouds in Landscape Negatives (see p. 28). Mr. Johnson exhibited a large number of very fine prints taken with the pantoscopic camera, amongst which were many of Braun's views of Swiss scenery on plates 20 inches by 9 inches, many possessing very fine clouds, and all having graduated and atmospheric looking skies.

Mr. WHARTON SIMPSON said that Mr. Johnson's remarks for the most part carried conviction with them, and that he had stated so much of truth that it was difficult to attempt to discuss or controvert anything he had said. All landscape photographers would doubtless desire to secure in one negative the clouds present in the sky as well as the landscape proper, and the means suggested by Mr. Johnson would often be efficient in enabling the photographer to secure such effects. But there was one point which, although it had been touched upon at the last meeting, had not received so much attention, he thought, as it deserved. Mr. Johnson had referred to the impertinence of securing, at one operation, the clouds and the

\* Continued from p. 22.

landscape upon which the shadow of the clouds was cast. But it should be remembered that in a very large number of instances the clouds which cast their shadows on the landscape were right overhead and quite out of the range of the lens producing the landscape, and there was no violation of truth, therefore, in the fact that the clouds seen in a picture were not those the shadows of which were on the landscape at all. He thought that the only point which could be insisted on in the introduction of clouds into a photograph was that they should be harmonious with the picture, and that they should not, by their character and lighting, violate natural or artistic truth.

Mr. BOCKETT said that all photographers would of course prefer getting the clouds in the same negative as the landscape, but for the great difficulty of the clouds always being overdone. He suggested the use of a mask inside the camera.

Mr. SIMPSON said that such a mask was used by Mr. Archer and other early photographers, being made at the time of a piece of brown or black paper torn to suit the horizon of the landscape.

The CHAIRMAN said the rapid movement of clouds caused much of the difficulty of securing them in the same negative as the landscape. The fact that in instantaneous pictures the clouds were often obtained with the same exposure as the foreground showed that it was not that the former required so much less light than the latter, but that their rapid motion destroyed their forms during long exposure. Mr. Johnson's suggestion was, if he understood rightly, to use a graduated diaphragm, which would, however, fail to meet the difficulty of the moving clouds.

Mr. JOHNSON said that the aperture in the pantascopic camera was generally wedge-shaped, or, in some cases, the sides were curved; but always so graduated as to give a gradually decreased amount of light from the foreground to the sky, in which the zenith received less, of course, than the horizon.

A general conversation on the subject followed, in which the Chairman, Mr. Werge, Mr. Taylor, Mr. Johnson, and Mr. Simpson, took part. Mr. Taylor said he tried various methods of securing clouds, but had not succeeded satisfactorily by any method except that provided by the pantascopic camera. Some members pointed out that the graduated sky produced by the wedge-shaped diaphragm was pleasing pictorially, but not natural. Others suggested that where a spire or other dark object projected beyond the horizon line would, with a graduated aperture, be underdone; to which it was answered that practically this was not the case, as such objects received a larger amount of light than lower objects.

Mr. BOOBY stated that he was in the habit of securing clouds by giving a graduated exposure with a flap shutter, which was gradually moved, giving finally an instantaneous movement for the sky.

After some further conversation and a vote of thanks, the proceedings terminated.

#### LONDON PHOTOGRAPHIC SOCIETY.

THE usual Monthly Meeting of this Society was held at the Architectural Gallery, in Conduit Street, on the evening of Tuesday, the 14th inst., Mr. J. GLAISHER, F.R.S., in the chair.

The minutes of a former meeting were read and confirmed.

Mr. GRIGG exhibited a block for printing with letter-press, together with the original drawing of the "Bowstring Hemp Plant," the printing block having been obtained by photographic means.

Mr. FRANK GOOD exhibited a desk-easel with reflector at the back, for enabling negatives and other transparent pictures to be readily retouched. The easel was provided with a series of loose frames to fit plates of different sizes.

Mr. J. R. JOHNSON exhibited a multiplying camera with some excellent contrivances.

The CHAIRMAN said it was nearly a year and a-half since he had occupied that chair, his absence having been caused by severe illness. Since then the Society had changed its meeting-room, and, as he noticed in the minutes of the previous meeting that the Chairman congratulated the Society on the change, he hoped that there was cause for congratulation, and that the Society would, in its new rooms, go on with increased prosperity. Since their last meeting, the Society and the science generally had suffered a severe loss in the death of his old and dear friend M. Claudet. There was no man who had done more to advance photography than he, none more ardent

in its study, none more willing, at all times, to give the results of his investigations freely to the world. At the recent meeting of the British Association at Dundee they had been much together, and had much conversation on the Society, and on M. Claudet's late work in connection with photography. Now he was gone; and he felt that he could not take that chair without a few words of kind remembrance of one whom they had often seen, and never seen without pleasure. By his death a vacancy was created in the Council, and it was proposed by the Council that his son should be nominated for election, at the next meeting, to fill his place.

Mr. SPILLER then read his paper entitled "Researches on the Hyposulphites and other Fixing Agents, Part I. (see p. 29). In the course of reading, he handed round for inspection examples of several salts referred to in the paper. These were: an example of hyposulphite of baryta; an example of hyposulphite of soda containing 17 per cent. of impurity, chiefly sulphate of soda, the appearance of the hyposulphite not suggesting adulteration; an example of hyposulphite of soda purchased many years ago, when that salt was 2s. per lb., was nearly quite pure. He also exhibited two samples of chromate of lead of the same constitution: one the usual chrome yellow, and the other of a rich red colour, the difference being that the latter was precipitated in the presence of a hyposulphite.

At the termination of his paper, Mr. Spiller exhibited some examples of prints treated in various ways to remove the final traces of silver from the whites of the print. With cyanide of potassium he had been enabled to remove every trace of silver from the whites, but not, unfortunately, without slightly injuring the general brilliancy of the print. By the use of hyposulphite of ammonia applied to a fixed print a considerable portion of the silver was removed, but not all. Adopting Mr. Bovey's suggestion for the employment of sugar in the printing bath, he had tried whether the silver in the albumen might be preserved in a soluble condition; but although he thought the whites contained less silver than usual, still it was not removed. He also exhibited some prints, to show a useful mode of mounting prints employed at the War Office. Perspective views of machines were produced by photography, and reduced photographs of mechanical drawings showing the same machines in section were mounted on the same card, showing the exterior and interior of the machine at one view.

After the Chairman had invited discussion,

Mr. ALLEN asked if it would be possible, instead of mixing the chloride salt with the albumen, to albuminize paper first, coagulate the albumen, and then apply the sensitive salts so as to keep them on the surface. He thought such a course would conduce to permanency.

Mr. HUGHES said the subject to which Mr. Spiller had devoted much attention—"How can we preserve our silver prints from fading?"—was one of vital importance; for, whatever might be the advantages of carbon, it was tolerably clear that silver printing must go on to a great extent for a long time to come, and the world could still be supplied with prints formed of albumen and silver. The question of securing permanency in such prints was one which Mr. Spiller had made peculiarly his own, and had already done much to solve the difficulty. But still much remained. The difficulty of Wedgwood and Davy was in fixing the image they obtained; and it seemed that, after all, we had but half conquered it even now. The enquiry in which Mr. Spiller was engaged was one in which photographers generally could take but little part, they could only express their interest in, and appreciation of, his labours, but not discuss the question or compare notes of experience.

Mr. J. R. JOHNSON said that photographers were much indebted to the labours of men like Mr. Spiller for such important enquiries. But he could not but feel that even when all should be obtained that was now sought in silver printing, they would not be much nearer to the end sought; namely, permanent prints. So long as silver was a metal peculiarly subject to the action of sulphur, &c., in the atmosphere, and suffered discolouration, so long pictures formed of silver, however perfectly produced, must be liable to deterioration and change. Mr. Spiller had given, as the best test for free sulphur, the immersion of a clean silver coin into a suspected solution, and its discolouration would at once reveal the presence of the smallest trace of free sulphur. And it appeared to him, therefore, that permanency was a quality to be sought by avoiding silver altogether.

Mr. HUGHES never intended to imply that absolute permanency could be obtained in silver any more than in carbon.

Even engravings would change by the discolouration of the paper. The whole question was one of degree, as there were the elements of destruction in everything. The presence of silver in the whites of the print where it was not required was one of their chief troubles, as it was there ready at once to register the action of any agency acting injuriously on silver, and show it in the most delicate part of the picture.

Mr. JOHNSON said that the question existed as to whether the silver in the whites was more sensitive than the reduced silver which formed the shadows of the print.

Mr. HART thought the great drawback to photographs was the lowering of the tone of the whites arising from the presence of silver there; and that if it could be removed the chief cause of fading would be got rid of. The reduced silver which formed the dark parts of the print were coated with gold, which would resist the action of the deteriorating agencies to which Mr. JOHNSON referred.

Mr. FRANK ELIOT said, that having already communicated the results of some experiments to the PHOTOGRAPHIC NEWS ALMANAC, he would not enter further into the question than to remark that the print which Mr. Spiller exhibited, in which he had removed the silver from the whites by cyanide, but had also injured the brilliancy of the print, had been too perfectly toned with gold to commence with. Probably, had it been less toned, left in a redder state, the result of the cyanide treatment would not have been so injurious. He would ask Mr. Spiller if he had tried the effect of a little cyanide mixed with the hypo fixing bath.

Mr. SPILLER had not, but thought the suggestion worth trying.

After some conversation,

Mr. SPILLER, referring to the remarks of Mr. JOHNSON, said that the gold toning upon the silver print was an important element not to be overlooked, and if a silver coin were coated with a very slight deposit of gold it would be effectually protected from the action of sulphur. He quite agreed with Mr. JOHNSON, however, that silver prints would always be subject to deteriorating influences.

The CHAIRMAN, in proposing a vote of thanks to Mr. Spiller, remarked that in his practice with the photographic registration at the Observatory they adhered now to the practice of twenty years ago, in using plain paper, in which the insoluble salt of silver formed in the albumen was avoided, and a better chance of permanency obtained.

After a vote of thanks,

The CHAIRMAN, in calling attention to Mr. Goode's easel for touching negatives, described a similar one he had in use at Greenwich. He also mentioned a curious fact, to the effect that having, in order to secure uniform temperature, removed their apparatus for photographic registrations into a room with little ventilation, they found that when the fire and gas had consumed the oxygen in the room, the action on the paper became much less perfect.

It was then announced that at the next meeting, besides the annual business, Mr. JOHNSON would read a paper on a new system of landscape photography.

The proceedings then terminated.

## Correspondence.

### REMARKS UPON THE CHEMISTRY OF PHOTOGRAPHY.

SIR,—Photography may be compared to gambling, the prizes being few and the blanks many. Yet there are good and bad photographers, just as there are good and bad card players. Games of chance, by the observance of certain laws, often bring success. Photography has its "lucky" ones; so has the turf.

A friend of mine has just told me of a person whom he supplied with instruments and chemicals; and, although he had never done anything before in the art, I am assured that he has taken in the first fortnight a number of very fine photographs. But my friend is afraid, as I am, that his success will ultimately turn out to be his ruin, for he is determined at once to commence professionally. No advice can prevail on him to wait; and, unless a bad case of fogging, followed

by other photographic diseases, immediately afflict him, a hundred to one he will be ruined.

"Tips" are not confined to the turf, for you can obtain photographic information that will relieve you of all your difficulties for 2s. 6d. in postage stamps. If that be too much to believe, why, you have only to send for that collodion and developer which never fail to give perfection. I need not say that if this were so, photographic failures would be almost unknown.

Before proceeding with any further remarks, I think it just to myself to state that this is a subject that I have undertaken to write upon only at the request of a number of friends. There were many weighty reasons for my diffidence, not the least of which was a reluctance to differ very materially with the first chemists and photographers of the day. This feeling amounted almost to a relinquishment of any publication whatever of the results of my experience. Selfish reasons have also had their weight; for I admit that it took some time to consider whether I would be just to myself by giving to the world what has cost me so much in money and time. But, after taking everything into serious consideration, I have determined to freely publish all that I know, on certain conditions—which conditions, if acted upon, will accomplish more in every way than a discussion, which would probably end in nothing of real value.

The wet collodion process has been practised by me professionally since its first introduction by Archer, and what I am willing to communicate has been known to me and tested for two years. I have read nearly all that has been published in English on the subject; but in no publication can I get an insight into the principles of photography, only a list of the different materials affected by light, and the numerous different formulæ for putting them together—some better and some worse, but all very imperfect, inasmuch as the very best seldom give the highest possible result, and when they do they cannot be depended on for any length of time.

The same failures which were inherent in the process on its first introduction belong to it yet. Whatever success some have attained can only be attributed to good manipulation, long practice, and, perhaps, quite as much as anything else, to an almost unlimited choice of material to mix and doctor as experience points out will suit different circumstances. This much is admitted by the majority of leading photographers, as they tell us they have nothing new to communicate.

Photography, as an art, has made giant strides; as a science, it lags behind. Better knowledge of its laws would enable us to enter new fields and gather richer harvests than any yet reaped. From my first connection with photography I have striven earnestly and constantly, sacrificing wealth, health, and comfort—in fact, most things a man values have I counted as nothing in comparison to success in realising an idea of certain chemical combinations that, in my opinion, would throw a new light on the foundations of the science, which idea I had formed before I was in practice twelve months.

Reason told me that what I was working for was quite possible, yet my innumerable experiments so disappointed me, as to often take away all hope of success; but still I persevered, and in time a certain success has rewarded my efforts. But there is much to be done yet, and the knowledge I have already gained has given me the master-key that is certainly destined to unlock every secret.

I will now endeavour to distinctly state what I have and what I can accomplish. First,—I can prepare my chemicals so that I can with certainty produce, consecutively, a great number of the highest class of negatives entirely free from every kind of imperfection; their production can be absolutely relied upon for a lengthened period, and quite out of all proportion to what can be accomplished by any published formula. For instance, I have produced from two ounces of nitrate of silver four hundred half-plate negatives. The chemicals were not altered in any way by me; worked

every day without giving a single failure. This work I set myself to do, and when done, everything remained in good order, and plenty of silver solution left.

To come at once to the object of this article: I will undertake, before any committee specially appointed, to produce, consecutively, 1,000 half-plate negatives, and, as before stated, perfectly free from imperfection. I will also point out the true cause of every failure, as well as remedy the following defects, viz., streaks in the direction of the dip, pinholes, fogging, hard, patchy, and thin negatives, needle points, greasy streaks, brain markings, marblings of various kinds, &c. I feel quite certain that I have a knowledge of the kind of change that takes place when light acts on iodide or bromo-iodide of silver; and I am not without hope of being able to demonstrate this, as I am fully persuaded it is a chemical one.

I am prepared for criticism that may not be favourable, especially as I have not published my process. Mere publication, without the demonstration I propose, would not settle anything, and would not be satisfactory, more particularly believing, as I do, that no published process that I have seen could possibly accomplish what I have asserted. But, should I be mistaken, I would like to have my error pointed out to me.

Now I must guard myself against being told of some one who has done as much before, and if their process be not published this will give them the first opportunity; for I have neither the time, talent, nor disposition to enter into a paper war to defend what I believe to be quite original.

As a proof of my sincerity, I am willing at once to communicate my process in strict confidence to any two or three scientific men acquainted with, but not professionally engaged in, photography; and, should they report favourably, it might sufficiently encourage those interested to appoint a committee, before which I would practically demonstrate my assertions—my only conditions being good light, in (say) July or August, as my engagements will not allow an earlier period. If, after proof, due credit be given to me, then I will give freely to the world all I know. This I will do regardless of Burns' advice—

"But still keep something to yourself,  
Ye scarcely tell to any."

Nothing shall I keep to myself, but be guided by the Arab proverb—

"Speak the truth, if the heavens should fall."

LACHLAN McLACHLAN.

Stamp Office Buildings, 9, Cross Street,  
Manchester, Jan. 1, 1868.

P.S.—Should my offer be considered worthy of attention, I will enter into an arrangement at any time for putting my statements to the proof; but I will not take part in any discussion, further than to explain anything that may not appear clear.—L. McL.

### ON THE USE OF DISTILLED WATER.

DEAR SIR,—I have just read Mr. Cherrill's article in the current number of the *News*, entitled "Against the Use of Distilled Water," and am, from my experience, compelled to disagree with him. If I were asked to state what I considered to be one of the chief causes of three-fourths of the failures in photographic manipulations and processes, I should unhesitatingly say, the neglect of obtaining absolutely pure water; and I may add, that so far from considering distilled water unnecessary, I am compelled to conclude from historic evidence that even that of the ordinary kind is mostly unfit for the chemist's use. It will be obvious to any one, after a moment's consideration, that the water of any locality contains traces, and sometimes more than traces, of the soluble organic and inorganic matters that abound in the soil through which it has to force its way; and, although it might be possible to find some spot where the water would contain no really noxious element, photographi-

cally considered—as Mr. Cherrill, perhaps, has done—yet I cannot deem it anything short of imprudent to advise photographers generally to disregard the use of the still, and employ the water nearest at hand.

Especially in the admixture of the negative bath is the various effects of undistilled water seen; and it is certainly "like straining at a gnat and swallowing a camel," to ask and pay for pure photographic silver and other chemicals, and then mix them with the unknown impurities obtained from the town reservoir or the local pump. In my own practice I have found it to be most profitable if, on adding a few crystals of nitrate to the quantity of distilled water selected for a new bath, there be the slightest milkiness, to withhold the remainder of the silver until a newly-distilled supply be obtained, in which this addition shall make no alteration to the bright and sparkling look of the water. In every case, I believe I may say, in which I have attempted to use a sample of water showing the slightest turbidity, the bath produced has had more or less of streak, fog, or other marking and deposit as the result. Hence my earnest advice to those whose successive failures have not made my words unnecessary, is, on no account trust your silver to anything but the purest distilled water; indeed, so far do I carry out my own injunctions, that not only in bath, developer, redeveloper, and other solutions is it used, but the first washing of prints is invariably that of uncontaminated water. To do this, of course, a still and appliances were necessary; but I conclude that no outlay has been of more benefit to me in the matter of creditable pictures, few failures, and comfort in work. I quite coincide with your correspondent, that no process which depends upon "uncertain conditions of success" ought to be, to say the least, preferred. I trust he will excuse me if the foregoing seem like "a hoist with his own petard;" and I am sure that as we become more and more familiar with our work we can afford to dispense with many things once considered indispensable on the authority of the "hand-books" he mentions; and that the fluttering expectancy and hope and fear of the novice is replaced by the quiet assurance of mastery in him whose theories have been nicely balanced and judged by his daily experience.—I remain, sir, yours truly,

R. H. P.

### INDIA-RUBBER MOUNTING.

SIR,—Seeing that several of your correspondents have had some difficulty in the use of the india-rubber mountant, I think it will be found that they have used the solution *too thin*: it should be of the consistency of golden syrup. The print and mount should be well coated, and the benzole allowed to evaporate thoroughly, before any attempt is made to mount the print. If the solvent has not quite evaporated before the print is pressed or rolled down, blisters will be almost certain to appear on some parts of the picture. I have used with success, for rubbing down the print, one of the globular glass-paper weights, passing it over every part of the print with considerable pressure.

I do not think the rubber mountant will ever be much used by professional photographers. It is better suited to the use of amateurs, who often keep their photographs in albums, and therefore always under a certain degree of pressure. I have given up the use of the india-rubber mountant since 1866, for on one occasion, not having time to send a series of large prints to be mounted by a professional mounter, I did them myself most carefully with india-rubber, but was much vexed at having them returned in a few days, they having blistered up from the mounts badly. I also had, until recently, in my possession some drawings which were mounted with india-rubber about the year 1850. These drawings had got loose from the cardboard, and there remained on the mounts a brown friable substance, as described in your article last week. I am, sir, yours obediently,

A PHOTOGRAPHER.

Plymouth, January 13th, 1868.

## SOAP IN DRY COLLODION.

SIR,—I see in your last number that M. Carey Lea has invented another "new dry process," which consists in adding tincture of soap to Sayce's collodio-bromide of silver. I beg to state that I have used soap in collodion for dry plates for some time, having adopted it in accordance with a suggestion of your own given nearly two years ago, when you recommended the addition of Castile soap to collodion to form oleate of silver as a suitable organic silver salt for dry plates. At the same time you recommended its use in collodio-chloride of silver; but that I have never tried. I have added two grains of Castile soap (sometimes I used soft soap) to each ounce of collodion, dissolving it first in the iodizer. It did not all dissolve, but there was sufficient to make a marked difference in the sensitiveness of the collodion when used wet, and also great increase of vigour. I have got good dry plates with simple washing, without any preservative. I gave it up, however, as I fancied it made the bath give foggy plates.—Very respectfully yours,

THOMAS HARNING.

P.S.—What is an "official tincture" which Mr. Lea says he has used? And does the novelty depend upon the use of this tincture?

[An official tincture is a tincture prepared according to the instructions of a recognized pharmacopœia, and generally kept ready for use by all pharmaceutical chemists. The tincture to which Mr. Lea refers is probably one known in America, but it is less certain whether it is usually kept in this country. We have a few remarks on the subject in another page. The novelty of the process consists in employing a new combination of known substances, and one which it appears produces a good result.—Ed.]

## EDGE'S PHOTOS.

SIR,—Seeing so many trying to solve the problem as to how the above-named photographs of portraits, with landscape backgrounds from nature, are taken, I, with your permission, will state how I think they may be done.

In the first place, take three pieces of patent plate glass, and get them finely ground at the edges until all are of one exact size. Next get a printing-frame that will open both back and front; at the back put in an ordinary hinged shutters, but leave depth enough of rabbet for thin piece of wood, round which I would double the sensitive paper, to keep it in its place; the front of the frame should be composed of a brass rabbet exactly the size of the patent plates (deep enough to take two pieces of the patent plates with spring fastenings to the four corners). So much for the printing-frame.

Now, with regard to photographing, in the first place take one of the three pieces of glass, and produce an ordinary stereo view, finished and varnished; with second glass take a portrait negative; with the third glass prepare a dry plate. When this is done, place it in the printing-frame with negative of portrait on the top, and produce a transparent positive over-exposed. In the next place, take your stereo negative, and prepare the face of it as a dry plate; when that is done, place it in the printing-frame, take your transparent positive, and print upon it negative, which will form a mask; any part that may be transparent to admit the light can be easily blotted out. Print the figure the proper depth; when that is done, remove that negative, and replace it by the stereo negative with photo mask. By this means I think the masks will exactly fit.—Yours respectfully,

A. E. SCALES.

Hartlepool, Jan. 8th, 1868.

P.S.—I also think that a thin solution of gelatine and bichromate of ammonium made very black with indian ink, and flowed over the face of landscape negatives, after being exposed under transparent positive, would make a very good mask: the shadows might be over-printed by means of a lens.

A. E. S.

[It will be seen that there is an analogy between the plan suggested here and that described in our last. It is only just to our correspondent to say that this letter was received before the publication of our last, but just too late for insertion in that number.—Ed.]

## DOUBLE PRINTING AND MR. EDGE'S PICTURES.

DEAR SIR,—In the method of double printing described in your last, I am sorry that I omitted to state that it will not do to print the negatives face to face, as the mask would be reversed; but some contrivance must be used to print the dry plate on the back, through the glass.—Yours truly,

W. I. MARQUAND.

Vauvert Street, Guernsey, Jan. 11th, 1868.

[Camera printing would meet the difficulty.—Ed.]

## Talk in the Studio.

M. ADAM-SALOMON.—A rumour has received some currency that M. Salomon is about to open a studio in London, having taken for the purpose the premises in Regent Street lately occupied by the United Association of Photography. We are in a position to state that there is no truth in this rumour. The premises in question have been taken by the proprietor of M. Ken's establishment in Paris. M. Salomon, as he recently stated in a letter in our columns, intends, during the coming spring, to visit London, but, in a recent letter, we are informed that the visit will, from press of business, not take place just at present. Whether his visit will be connected with any idea of opening a studio here, or not, we cannot at present state; but, in any case, he will bring with and place on view a collection of his portraits, both prints and negatives.

LITHOGRAPHIC TRANSFER PAPER.—Our contributor, "A Practical Man," sends us the following, in answer to a recent enquiry by a correspondent:—"The preparation of paper for transfer in the lithographic process is now very much simplified, amateurs and others being supplied with a peculiar kind of ink, invented and made by Haddon and Co., of George Yard, Lombard Street. It has great advantage over the old ink, which was difficult to manipulate with. This new preparation is easy of use, cheap, and quick. Any can use it, and prepare circulars, forms, or outline designs for the lithographic printer with great readiness and certainty, no prepared paper being required, any good smooth flat-faced paper answering well."

EXHIBITION OF MEDALLISTS AT THE CRYSTAL PALACE.—The directors of the Crystal Palace are inviting all persons who received medals at the Paris Exhibition to contribute the articles for which they received medals to an exhibition to be held in the Palace. Photographers who received medals, in responding to this invitation, will, in many instances, have an opportunity of improving on their Paris contributions.

MORE PIRACY.—A few days ago, at the Birmingham Police Court, a man named Robson, a wholesale photographer, carrying on business at the Green Lanes, near Birmingham, was summoned by Messrs. Graves, of London, on a charge of pirating registered photographs, the property of the complainants. Having reason to suppose that pirated copies of their photographs were being disposed of wholesale, Messrs. Graves sent a young man named Cattermole to Birmingham. He assumed the name of Milner, and, on the pretence of desiring to purchase, he got introduced to Robson, who sold him, as it was alleged, pirated copies of "The Piper and the Nutcrackers," "Ordered on Foreign Service," "The Acquittal," "The First Sermon," "The Second Sermon," "Waiting for the Verdict," and other pictures. The defence set up was that the pictures sold were photographs of engravings, not copies of the complainants' photographs. The Bench, however, were satisfied with the evidence for the prosecution, and fined the defendant £65—that is, £5 in thirteen cases—with the option of going to prison for twenty-six months.

## To Correspondents.

CULLUMPTON.—As your queries require answers which may be interesting to others, we print them in full, with their answers:—  
1. In making the collodion for the new dry process (soap in collodio-bromide of silver) is no gun-cotton to be used? I thought all collodion was made with that substance.—The

omission of any mention of soluble cotton in Mr. Lea's formula for collodio-bromide is doubtless an inadvertency. Add to each ounce 5 or 6 grains of cotton. The exact quantity must somewhat depend on the quality of the cotton. 2. In making a solution of india-rubber in benzole, for edging plates, &c., is any particular kind of rubber necessary? for I put 2 grains of good india-rubber into an ounce of benzole, about a week ago, and hardly any change seems to have taken place, except that the piece of rubber is larger in look and thinner—more transparent in fact.—Samples of india-rubber vary much. Old samples which have been much exposed to light become comparatively insoluble. Some samples of benzole also are bad solvents. It is wise to adopt the recommendation we have given, to macerate first in a small quantity of chloroform. 3. In using the old hypo-toning and fixing-bath, does it imply, when it says: "the solution, too, is always ready and in good working condition to receive the prints direct from the pressure-frame, without any previous washing," that it is better *not* to wash the prints before immersion, or merely that the prints need not be washed?—The custom used to prevail of immersing the print in the old toning bath of gold and hypo without washing, but we do not recommend the practice. 4. When making up the sulphocyanide of ammonium toning-bath, as soon as I put in the gold solution, a yellow-coloured precipitate was formed, and still remains at the bottom of the bottle: is this usual, and does it interfere with the toning?—The orange-coloured precipitate is sulphocyanide of gold, which is insoluble in water, but it is soluble in excess of the alkaline sulphocyanide. If you add, therefore, more of the sulphocyanide of ammonium the precipitate will be re-dissolved. Unless you re-dissolve it you waste the gold. 5. I have in my possession a carte-de-visite lens, 41-inch focus, 2 1-10th in diameter, and about 16 feet from sitter: is this a thoroughly good lens to use and keep, or ought I, to obtain perfectly good results, get one of longer focus?—A lens of longer focus is desirable for card pictures, especially for standing figures. 6. Why is it that portraits can't be, or are not, taken with a large single lens? Is it merely because it requires a longer exposure? Groups I can take well with a 3-inch Ross single lens: why not take one person? I have not tried yet except in my studio, where it was too dark.—Portraits can be taken with a single lens, but if taken with large aperture, to secure rapidity, the definition is not good; and if the aperture be reduced to get good definition, the exposure is long. You can take single figures, of course, just as well as groups, with your single lens. 7. Might I unke and copy a registered tent for myself and private use without incurring any risk of breaking patents, &c.?—Registration does not protect the design of a tent, but a patent does. If you copy a patent tent you break the law, but this is not the case with registration. 8. I have recently had a quire of albuminized paper from a surplus stock of —. I find that it prints a curious purple colour, not a brick-brown, as is usually the case: is this peculiar to some papers? I send you a piece just out of the pressure-frame; some pieces are much more purple—indeed, almost a nice tone—but the enclosed is hardly pleasant.—The colour of the untuned prints enclosed is not uncommon, and is very good; such prints generally tone well. 9. Do you know any thing of —'s albuminized paper, whether it is a good sample?—The paper of the maker whose name you mention is very good.

W. H. J. asks if any of our correspondents have tried coffee dry plates developed with iron and silver, and intensified with acid pyro and silver, and adds that he has had fair success with some plates so treated. We have not heard of cases, but shall have pleasure in recording the results of any of our readers. 2. Mr. R. Mauners Gordon considers the gun process, as described in our YEAR-BOOK, the most perfect dry process, equal in sensitiveness to any other he has tried, superior in results to most that he has tried, and superior in keeping qualities to all that he has tried. Being an ardent dry-plate experimentalist, he has got good results by many of the known processes, and has found the honey process useful for many purposes, especially where simplicity rather than keeping qualities is required; but his verdict, on examining all, is that which we have just given. The reason for his abandonment of the modification of the collodio-albumen process was its imperfect keeping properties.

R. M. D.—The YEAR-BOOK is not out of print. We have seen the prospectus to which you refer. You are right in supposing that it reaches you without our sanction. After copies of the YEAR-BOOK or NEWS leave our publishing office we have no control over them, and they may be made the means occasionally of surreptitiously conveying documents of which we have no knowledge. It is possible, as you suggest, that it is an attempt to take advantage of any little prestige belonging to the amateur publication we have recently noticed. It is purely a trade speculation, its projectors being men of no position or reputation, and whose names would carry no weight in the photographic world.

HILLERSDON.—Much depends on the colour, character, and general tone you prefer. We described the mode of toning transparencies on dry plates in an article which appeared a few weeks ago. You will also find an article on the subject in our last YEAR-BOOK. Any dry process of which you are master will answer. As a rule, the addition of acetic acid to the pyro developer will tend to the

production of a brown tone; the use of citric acid, to a bluish black tone. It not unfrequently happens that dry plates receiving full exposure have a trace of an image before development, especially if the preservative used contains a reducing agent, as in this instance.

PHOTOGRAPHER.—If you have any reason to suppose that any trace of a gold salt remains in solution, you may, instead of pouring away the solution, add chloride of lime to it, taking care to add sufficient nitric acid to give an acid reaction. This will combine with the lime, and liberate the chlorine and hypochlorous acid. The chlorine will combine with the gold in a fine state of subdivision, and also with any oxide of gold which may be in solution. A solution of hypochlorite of lime is made by adding common bleaching powder to water, shaking, and then filtering. You obtain in the water chlorine and hypochlorite of lime, and leave a residue of hydrate of lime. A gentle heat will promote the solution of the gold, and the hypochlorite solution is to be added, a little at a time, until all is dissolved. The subsequent boiling is to get rid of excess of chlorine. In a toning bath made with carbonate of soda, the bath often becomes inert before the gold is thrown down, a little oxide of gold remaining in solution, which is eventually thrown down as metallic gold. We do not quite understand what you mean by the spongy precipitate formed in mixing a neutral silver bath. There should be no precipitate at all. We cannot recommend special lenses by name in this column. If you will make a list of the lenses you contemplate selecting from, distinguishing each by a figure or a letter, we will give you our opinion as to which is most suitable to your purpose.

A FIVE YEARS' SUBSCRIBER.—Professor Fowler is an American gentleman contributing to American journals. We generally reprint such of his articles as appear likely to interest our readers, but we have no knowledge of the subjects upon which he will write, and when. We have published all that we know he has written on the subjects you name.

O. F. OTTO.—A minim in fluids is equivalent to a grain in solids, 480 minims forming one measured ounce. As a somewhat rough rule, minims and drops have been regarded as sufficiently equivalent to be used in many cases. The rule is, however, obviously very unsafe, as drops of different fluids vary considerably, not only in weight, but in volume. A drachm-glass measure is generally graduated for minims.

J. H. S. STANLEY (Texas).—There are various modes of producing the effects to which you refer, but the following method will, when well-managed, give exceedingly fine effects, closely resembling ivory painting. Take a perfect print of somewhat warm tone, clean, sharp, and not too deeply printed, but still sufficiently made out. Instead of mounting on board, stretch the print on a frame made by cutting out a piece of millboard, attaching the print at the edges, colour in water colours, using all the tints considerably more vivid than is required in the finished picture. When completed, melt a little white wax or paraffine, and apply it at the back of the picture, using just sufficient to make it semi-transparent and no more. A piece of pure white paper, or cream-coloured paper, is then placed at the back of the print, which very closely resembles an ivory miniature. A few touches of high light may be put in body colour on the face with advantage.

HENRY H. HELE.—Elementary works on art suitable for photographers are not very plentiful. One of the simplest and cheapest we know is Howard's Sketcher's Manual, published by Darton and Co., at about 5s., we believe; but we fear it is out of print. Burnet on Composition is a capital book, but a little expensive, the price being 15s.; published by Leighton, Brewer Street, W. But to acquire a satisfactory knowledge of the art principles which govern pictorial effect, especially as possible in photography, requires the study of many books, and much study. We have had for some time in preparation a series of lessons on the principles of art as applied to photography, contributed by more than one of the most celebrated artists associated with photography. These will commence in our pages very shortly. "Leaf Prints," by Professor Himes, has no publisher in this country, but could, doubtless, be ordered by your bookseller through a London house.

R. H. P.—The article on M. Salomon's studio and manipulations will appear in our next. Of course the addition of sugar to the printing bath would nullify the value of an argometer based on the specific gravity of the solution. We saw the groups of which you speak, by M. Angerer, in the Exhibition, and noted the excellence. We rather infer the skill of the artist, however, than any special quality of the lenses employed, inasmuch as whilst the lenses are accessible to all, the excellent groups are only produced by one or two artists. Further, M. Angerer, to our knowledge, employs for much of his work the lenses of one of our best London opticians. For the groups, we have no doubt that lenses of long focus are used, and the figures are admirably arranged to suit the exigencies of the lens. Doubtless the light at Passy is excellent. The card enclosed is very rich and brilliant.

JAMES INGLIS.—The cards and cabinets duly received. Thanks. We shall notice them shortly.

RECEIVED.—"Monckhoven's Photographic Optics."

Several articles in type and completed stand over until our next. Several Correspondents in our next.

### ENLARGING BY THE MAGNESIUM LIGHT.

MR. SOLOMON has recently called our attention to his apparatus for producing enlargements by means of the magnesium light, and given us an opportunity of witnessing its practical application, the results of which, we must confess, decidedly exceeded our anticipations. From the experiments we have witnessed it appears that nothing can be more simple, certain, successful, or economical, than the operation of producing enlargements by the appliances thus provided.

The instrument employed in the experiments at which we were present is the smallest provided for this purpose. It consisted of a camera with a portrait lens for enlarging, of about four inches focus; behind this a groove for holding the negative to be enlarged; and behind again, a magic-lantern condenser, the combination consisting of a double convex and a meniscus lens, the combined focus being three inches and a half. The magnesium lamp, with a clock-work arrangement, to maintain a steady delivery of the wire or ribbon for three minutes, is attached to the back of the camera, the ribbon passing through a tube into a wide metal tube or chimney inside the camera; an opening in the tube, the back of which serves to some extent as a reflector, permits the light to reach the condenser. The chimney projects beyond the camera, and a tin pipe serves as a flue to conduct any smoke into the open air. The whole arrangement is compact, neat, and easy to manage.

The first picture we saw produced was from a card negative, the head and bust of which were enlarged to fill a whole sheet of photographic paper, the amount of enlargement, estimating without actual measurement, being about ten diameters. The mode of preparing the paper, which was used nearly dry, was an experiment, and it was not anticipated that the exposure would be short. A single piece of ribbon was burnt for about two or three minutes, and the image, a faint indication of which was visible, was then developed with gallic acid containing acetic acid. A very good picture was obtained, with a trace of under-exposure, but fully equalling the average of solar camera pictures we have seen.

In the next experiment all the conditions were well defined, and the results very perfect. The paper was salted by floating on a solution containing 15 grains of iodide of potassium and 5 grains of bromide of ammonium in an ounce of water. The silver bath contained 60 grains of nitrate of silver and 10 minims of acetic acid to each ounce of water, and the paper was used immediately after floating on this bath, and whilst it was still wet. The amount of enlargement was about six diameters; that is, the head, in the negative of which the head and bust were produced was about half an inch long, was enlarged to about three inches long. The exposure was exactly thirty-five seconds, with

the light from one piece of ribbon. No trace of the picture was necessary in the process; but on applying a hot solution of gallic acid the image rapidly appeared, and, after about three minutes' development, was fully out, at once soft, round, and vigorous, clean in the lights, and deep in the blacks, and an exceedingly good enlargement was produced.

The ribbon used in these experiments runs about fifty yards to an ounce of magnesium, one yard burning for three minutes. Thus, at twelve shillings and sixpence per ounce, each minute's light cost one penny. A small portion of the ribbon is burnt in illuminating the negative during the process of focussing; but this, together with the exposure on the sensitive paper, did not exceed one minute, so that in this instance the cost of the light for an enlargement of about six diameters was about one penny. For an enlargement to life-size, which, as a rule would be effected from a negative not requiring more than an enlargement of ten diameters, the combustion of wire would probably not exceed one yard, costing threepence.

The results produced, so far as the light was concerned, leave little to be desired. A certain degree of unsteadiness and flickering, which belong to the magnesium light, at times produced much less difficulty than we had anticipated, only serving to make exposure a little uncertain, and requiring the exercise of judgment in the operator, much the same as exposure in a landscape, with rapid alternations of sunshine and diffused light.

We were, as we have said, altogether unprepared for such a degree of excellence, and at such a comparative economy in the cost of light. This method of enlarging is well worthy of the attention of all whose wants will be met by means of development printing.

### IMPORTANT COPYRIGHT CASE.

A RECENT decision of the Lord Chancellor in a case of photographic copyright brought before the Court, is most important and interesting to photographers and all interested in the publication of works of fine art. The number of singular decisions which have been given by police magistrates where, in accordance with the provisions of the statute, a remedy has been sought against piracy by summary process, and the indisposition which has been manifested on many such occasions to recognize copyright in a photograph, has led many photographers to regard the Act of 1862, so far as it concerned their art, as little better than a dead letter. In a suit instituted in a higher Court it is refreshing to find an entire absence of the petty feeling which seems to have governed the decisions in many of the cases to which we have referred, and in its place a straightforward administration of the law in accordance with the evidence brought forward.

The reports of the daily press of the case to which we refer—*Strahan v. Graham*—have already appeared in our pages. We have recently been favoured with a perusal of the short-hand writer's notes of the case, and as the recent decision of the Lord Chancellor for the first time strictly defines and authoritatively lays down the law of fine arts copyright, we shall now lay before our readers such a statement of the facts and the decision as will clearly set forth the position of photographers in relation to copyright in their works, and in relation to any assignment of such copyright to others for publication, either of the pictures themselves, or copies of them produced by any process.

COURT OF CHANCERY, DEC. 20, 1867.

(Before the LORD CHANCELLOR.)

STRAHAN v. GRAHAM.

This was an appeal by Mr. Strahan against the judgment, in February last, of Vice-Chancellor Sir R. Malins. On the 20th ult., after two days' hearing, the Lord Chancellor affirmed the decree of the Vice-Chancellor, and dismissed the bill with costs.

In November, 1864, Dr. MacLeod, the editor, and Mr. Strahan, the publisher, of "Good Words," purchased from the defendant, Mr. Graham, for the purpose of illustrating in "Good Words" Dr. MacLeod's *Travels in the East*, some of the photographs taken by the defendant in the Holy Land. In making this agreement, which was verbal, the defendant reserved to himself the copyright of these views, and the right of publishing them as photographs, or otherwise, in any other publication. At settling in August, 1865, the defendant refused to sign the receipt as prepared by Mr. Strahan, which was "for the photographs used in 'Good Words,' but signed the receipt on its being altered to "for the use of photographs in 'Good Words,' as per account rendered, (defendant) reserving all rights to issue the same, either as photographs, engravings, &c., in any other publication."

On 31st January, 1866, Mr. Strahan published Dr. MacLeod's "Eastward" as a fourteen shilling volume, containing the same illustrations from the defendant's photographs as had appeared in "Good Words," 1865. Thereupon an action was instituted by Mr. Graham in the Court of Queen's Bench against Mr. Strahan, suing for damages, and for an injunction to restrain the sale of the book. N.L. It was to stay that action, and to compel the defendant to grant Mr. Strahan a licence to use his engravings of the defendant's photographs for any purpose he chose, that the Bill of Complaint was filed by Mr. Strahan.

On 18th and 19th February, 1867, this Bill was discussed before Vice-Chancellor Sir R. Malins, and dismissed with costs. Thus the licence craved was not granted, and the sale of the book was restrained.

Mr. Strahan appealed to the Lord Chancellor. On the 19th and 20th ult. the case was heard, and, at the close of the arguments, the Lord Chancellor affirmed the judgment of the Vice-Chancellor, with costs.

It is therefore now ruled—

That the copyright of any photograph or other work of art remains in the artist, or author of such work of art, in so far as he does not part with the same.

That the blocks from which wood engravings are printed do not carry the copyright of these engravings; in the same way as the types or stereotype plates from which a book is printed do not carry the copyright of a literary work.

That every sale of arts copyright, or licence of user, must be in writing, and cannot be construed to extend further than is expressed in that writing.

It may be important here to remark that the copyright of any photograph, or other work of art, only vests in the author or producer in cases where the picture has been produced by the artist for himself, and not as a commission for which a definite consideration is paid. The professional photographer, in taking a portrait or view to order, does not acquire a copyright in such photograph unless he reserve it

by a memorandum in writing, signed by both parties, to the contract at the time. But any portrait or view taken by the photographer by his own choice secures, on registration, an absolute copyright in the photograph, of which he cannot be deprived by any sale of copies, or of a limited right to copy for any specific purpose, except by an assignment made in writing. On this point the judgment of Vice-Chancellor Malins was very specific, observing that if Mr. Strahan had "proved a verbal contract, the objection would have been as fatal here (in the Court of Chancery) as at common law; that the statute requires to be in writing."

Another point of interest to our readers, of a non-legal character, is worth observing, as illustrating the value of the copyright in good photographs. Under the contract with Mr. Graham Mr. Strahan bought the right to engrave seventy or eighty photographs for use in "Good Words," only at the rate of three guineas each; and rights to copy the same photographs for other works had also been sold to Mr. Murray, to Mr. Longman, Mr. Bentley, and Mr. Day. The photographs were very fine and rare ones, and the price was reasonable; but amid the general prevalence of a tendency to produce photographs at disgracefully low prices, it is pleasant to contemplate cases in which examples of photography are regarded as works of art, and are valued in such a spirit in the market.

#### THE LATE C. THURSTON THOMPSON.

It is with very deep regret that we chronicle the loss to the ranks of professional photography of another of its distinguished ornaments, and a very estimable gentleman. Mr. C. Thurston Thompson died on the 20th instant, at Paris, after considerable suffering. He had been out of health for some time, gall-stones, causing jaundice, being the final form of illness.

Mr. Thompson was the son of the well-known wood-engraver, Mr. John Thompson, whose name is associated with much very excellent work, and especially with the engraving of Mulready's design for the first penny postage envelope. Mr. Thurston Thompson was brought up to his father's profession; but early in the history of collodion photography he became a pupil of Mr. Bingham's, of Paris, and has in subsequent years devoted himself largely to the same class of work as Mr. Bingham. As a photographer, Mr. Thompson had, in his especial vocation of reproducing works of fine art, very few equals, his refined taste and extensive knowledge of art peculiarly fitting him for the duties which, as photographer to the Department of Science and Art at South Kensington, for many years devolved upon him. His photographs, recently produced, of historical architecture of Spain, also for the Department, are amongst the choicest examples of architectural photography in existence.

Mr. Thompson was a man of extensive and varied art culture, possessing a most discriminating taste and judgment; but, withal, modest and unassuming. As a private friend he was a rarely amiable man, possessing an unusually winning and conciliatory deportment. He was for many years a member of the Council of the Photographic Society, where, when at home, he was found in regular attendance. His residence for some time in Spain and Paris, during the last year or two, has caused his absence from the deliberations of the Council for some time, an absence always regretted, and which it will cause a deep sorrow in all his colleagues to know will never now be broken. He died in the full prime of life, his age, we believe, little exceeding forty years.

#### AN ART CRITIC ON THE TOUCHING AND LIGHTING OF M. SALOMON'S PORTRAITS.

THE Art Critic of the *Illustrated London News*, a gentleman whose sound remarks on art and intelligent appreciative comments on photography we always read with pleasure, has

some recent remarks on the subject of the touching and the lighting of M. Salomon's portraits which, as our statements on the subject are referred to, demand from us a few words of explanation. We will quote the paragraph in its entirety, so far as it relates to the question of touching. Our contemporary says:—

We are informed that M. Adam-Salomon, of Paris, who, it is generally conceded, is the best portrait photographer in Europe, intends shortly to visit this country, bringing with him examples of his art. Apropos of this announcement, we remark that a controversy as to whether the portraits by M. Salomon in the last exhibition of the Photographic Society were or were not "touched" has been maintained with some animation. It may be remembered that, in reviewing these marvellously beautiful works, we expressed ourselves morally certain that several of them had been touched, some of them extensively; and we did so notwithstanding that the PHOTOGRAPHIC NEWS had expressed itself convinced, after minute scrutiny of negatives and prints in Paris, that both "were alike guiltless of any touch whatever from the pencil of the artist." At the same time, we were careful to insist, lest British photographers should delude themselves by attempting to extenuate their defeat, that the essential merits of M. Salomon's productions were independent of adventitious aid from the pencil. Our opinion on the question of after-touching has been confirmed in many quarters; and even the PHOTOGRAPHIC NEWS says, in a subsequent number, "there is in many prints the retouching common amongst all photographers, such as the strengthening of the iris or pupil of an eye, &c.; on some there is here and there a boldly-hatched line, to give force or form to some portion. . . . Individual parts—such as an eye, a hand, or a lock of hair—have been often improved by clever touches." Now, we had always understood that the only admittedly legitimate "retouching" common amongst all photographers "was merely stippling out accidental spots or blemishes; but that any tampering with 'individual parts,' to give 'force or form,' was deemed highly objectionable, as diminishing the accuracy, and therefore the, so to speak, documentary value of the pure photograph. Moreover, as the PHOTOGRAPHIC NEWS now acknowledges that many parts have been "improved" (?), may not an eye familiar with every recourse of water-colour painting detect that more extensive blending of the gradations in the flesh which we believe to exist in several of the exhibited specimens? After all, however, where the retouching is so exquisitely artistic, it might almost appear as justifiable, regarded solely from the artistic point of view; and in any case we are quite prepared to believe that some of M. Salomon's finest works are virtually untouched.

Our contemporary—we are satisfied, unintentionally—somewhat mistakes the tenor of our remarks upon M. Salomon's portraits. In speaking of individual pictures, and these often the best, we have said that they were guiltless of any touch from the pencil of the artist; but speaking of M. Salomon's pictures as a whole, we have said and repeatedly reiterated, that some of them were considerably touched, some a little touched, and some quite untouched. We unhesitatingly agree with our contemporary, not only that, in some cases, there is the bold and indisputable touch which removes some fault or gives force to some beauty, but that there is also, in some cases, "the more extended blending of the gradations of the flesh" of which he speaks. We have said more: we have expressed our conviction that M. Salomon was too much imbued with the feeling of an artist to neglect the application of the pencil in any case where he could remove a fault or add a beauty to his pictures. The point upon which we have insisted is just that in which we are confirmed, and is so well expressed by our contemporary, that "the essential merits of M. Salomon's productions were independent of adventitious aid from the pencil." We have aimed constantly to impress upon photographers the fact that it was to art knowledge applied photographically that the excellence of the pictures was due; that art knowledge and artistic feeling in the pose, arrangement, and lighting, rather than in the application of the pencil, were the sources of superiority. We felt it necessary to insist upon this because it was tolerably freely rumoured amongst photographers that the photographs themselves were entirely overlaid by the pigments of the miniature painter; and that, therefore, they did not enter the lists honestly when they competed with photography proper. As such an impression was unfair in itself, and mischievous in its operation, because it deprived English photographers of the valuable lesson

that they had a higher excellence to attain by means legitimate to their art, we have persistently insisted on the fact that the pictorial value of the portraits was not due to retouching, and that where it was employed it was only used to supplement photography, not to overlay or supersede it; and having seen both negatives and prints in every stage of their production, we were able to do this with some show of authority for our statements.

On the question of the legitimacy of "improving" a photograph by retouching, opinion amongst photographers has undergone considerable change of late years, and the fanatical faith in the photograph pure and simple has undergone much modification. The oldest photographers, both in landscape and portraiture, do not hesitate to apply the pencil to either negative or print to remove a blemish or give additional force to a fine point in a picture. The only conditions necessary in adding such supplemental touches are honesty and skill to avoid the falsification of nature or the violation of artistic truth; and success in improving his picture within these conditions is the touchstone of the legitimacy of the operation.

On the subject of the mode of lighting, our contemporary made some remarks, in his criticism of M. Salomon's pictures at the late exhibition in Conduit Street, to the effect that they were manifestly produced by means of a light from a confined source. In regard to many of the pictures this statement is indisputably true; the strong cast shadows present in many of them were evidence of this. In a "Lesson Learned in Paris, by a London Photographer," the writer, describing what he saw in M. Salomon's studio, expresses his conviction that he did not work with a concentrated or confined light. Noticing this, our contemporary says:—

The writer in question says that, contrary to our opinion, M. Salomon does not employ a confined area of light; and yet, forthwith, the writer proceeds to prove that we were perfectly right in our conjecture. He says that M. Salomon "carefully kept all the light in one direction (for he has carefully excluded it on one side, up to the ridge of his roof). . . . He has stippled down completely the violence of the top-light." Further on, the superior results of the foreign portraits are attributed to the Continental photographer's superiority in the management of lighting. And, again, the writer adds, "the superior rendering of light textures is due, I feel assured, to their superior light, which enables them completely to moderate the intensity of the top-light, and to employ the pure light from the side, and only sufficient of it to produce those masterly touches of brightness we all so much admire." It is evident from this that M. Salomon resorts to various expedients to subdue all light relatively to the ray he wishes to be paramount; ergo, may it not be said, without fear of misconception, he works with a confined light? Otherwise, he could never secure the effects we all admire. So much, as an artist, M. Salomon well knows; so much is absolutely certain from, as we before remarked, the definition of the cast shadows in his portraits. Once having secured a principal and comparatively confined light, it is of course for photographers to decide what further area of light, provided always it be of secondary intensity, may be necessary for their operations.

In this matter both gentlemen are right. M. Salomon unquestionably frequently works with a concentrated light, or a light from a confined area. His principal light is a high side-light. This is obtained through the only clear glass in his studio, the space it occupies being twelve by six superficial feet; as much of one-half of which is frequently covered by blinds. The only skylight possesses about double that area of glass, the whole of which is obscured by stippling with white paint, and a portion of the soft light admitted by this is occasionally cut off by blinds. When the "London Photographer" saw the studio, it was in November, and, as may be naturally supposed, the area of light admitted was less limited than usual, and the pictures produced at the time, whilst in nowise inferior in excellence, were not distinguished by the brilliant contrasts of light and shade present in some of M. Salomon's portraits. Nevertheless, the "London Photographer," who described his own experiences, is one of the ablest and most conscientious exponents of our art; and the difference between him and our contemporary is one rather of words than facts.

A word on another subject, and we are done. The Art Critic of our contemporary calls attention, "for the sake of literary fairness," to certain garbled quotations from his former remarks, made by the "London Photographer" in question. He says:—"For example, we spoke of *spotty lights*, not frothy lights; we spoke of the light an artist chooses for his studio, not for his shades (!)" We hope it is scarcely necessary to assure our contemporary that the errors in question are either clerical or printer's errors, most probably the latter. Our contributor is utterly incapable of the meanness of an intentional misquotation, which would here, moreover, be not more mean than purposeless and foolish.

## PICTORIAL EFFECT IN PHOTOGRAPHY;

BEING LESSONS IN

COMPOSITION AND CHIAROSCURA FOR PHOTOGRAPHERS.

### INTRODUCTORY REMARKS.

"All arts having the same general end, which is to please; and addressing themselves to the same faculties through the medium of the senses; it follows that their rules and principles must have as great affinity as the different materials and the different organs or vehicles by which they pass to the mind, will permit them to retain."

"As our art is not a divine gift, so neither is it a mechanical trade. Its foundations are laid in solid science; and practice, though essential to perfection, can never attain to that which it aims unless it works under the direction of principle."

"Every opportunity should be taken to discountenance that false and vulgar opinion that rules are the fetters of genius; they are fetters only to men of no genius; as that armour which, upon the strong, is an armament and a defence, upon the weak and mis-shapen become a load, and cripples the body which it was made to protect."

"It must of necessity be that even works of genius, like every other effect, as they must have their cause, must likewise have their rules; it cannot be by chance that excellences are produced with any constancy or any certainty; for this is not the nature of chance."—*Discourses of Sir Joshua Reynolds.*

"In a word, every art, from reasoning to riding and rowing, is learned by assiduous practice; and if principles do any good, it is proportioned to the readiness with which they can be converted into rules, and the patient constancy with which they are applied in all our attempts at excellence."—*Dr. Thompson's Outlines of the Laws of Thought.*

It has often been asserted that the artist, like the poet, is born, not made; and, within certain limits, the assertion is doubtless true: without a natural capacity for pictorial perception no study and no amount of industry would produce an artist. "Patience and sandpaper," Ruskin remarks, "will not make a picture." But, no matter how great the natural capacity, or how undoubted the genius, certainty in excellence, and permanent success, cannot be attained without a knowledge of the rules and a study of the principles upon which pictorial effect depends. No mistake is more fatal than a reliance upon genius instead of effort, upon "inborn taste" instead of culture and the application of recognized and certain laws.

It has been often alleged, that except in its lowest phases, and in its most limited degree, art can have nothing in common with photography, inasmuch as the latter must deal with nature, either in landscape or portraiture, only in its most literal forms; whilst the essential province of art is to deal with nature in its ideal forms, rendering that which it suggests as well as that which it presents, refining that which is vulgar, avoiding that which is common-place, or transfiguring and glorifying it by poetic treatment. Photography, it has been said, can but produce the aspects of nature as they are; and "nature does not compose: her beautiful arrangements are but accidental combinations." But it may be answered, that it is only the educated eye of one familiar with the laws upon which pictorial effect depend who can discover in nature these accidental beauties, and ascertain in what they consist. Burnett observes, "Nature unveils herself only to him who can penetrate her sacred haunts. The enquiry, 'What is beautiful, and why?' can only be answered by him who has often asked the question." The same writer, speaking of Turner's early efforts, describes them as something like very common-place photographs; they were water-colour landscapes, "aspiring only to topographical correctness, the unadorned represen-

tations of individual scenes." It was only subsequent study, and a higher knowledge of the resources of art, which "gave him a hint that selection of a situation, and clothing it with effective light and shade, ennobled the picture and placed it more in the rank of a composition than a plain transcript." The same is equally true of portraiture. Although likeness is the quality of first importance, artistic arrangement is scarcely second to it. In some cases, indeed, art-excellence possesses a wider and a more permanent value than mere verisimilitude. The portraits by Titian, or Velasquez, or Reynolds, live rather as pictures than as likenesses, and the Gervartius of Vandyke excites the admiration of thousands who scarcely bestow a thought on the identity of the original. Art-culture, however, materially aids in securing likeness by teaching the eye rapidly to seize the salient features, to determine the most suitable view, and to arrange the light so as to bring out the effect of character; at the same time giving force and prominence to natural advantages, and concealing or subduing natural defects.

It is unnecessary however, to enforce here the value of art culture and the advantages of a study of such part of art as can be reduced to rule and law, or stated in broad principles. A growing appreciation of the importance of the subject exists amongst photographers, and an increasing desire to be put in possession of the means of studying pictorial science. The enquiry has constantly been reaching us of late, "How shall we begin to study art? Where shall we find instructions?" Of course it was easy to give the answer that the same sources of information, the same aids to study, were open to the photographer which were available to the painter. But this scarcely meets the case: the training in drawing and other elementary portions of the painter's art brings with it a gradual familiarity with higher art study, whilst the chemical and mechanical nature of the photographer's technical training does not necessarily bring him into contact with pictorial effects. Schools of art, academy lectures, &c., do not exist for him. Works on art of course there are, and many of them very excellent aids to the student; but they are all written with a direct reference to other modes of expression or application than those possible to the photographer, whose tools and materials are less plastic than any hitherto familiar to the artist.

In photographic literature there has been much fragmentary treatment of art, and some of it by blind leaders of the blind. In an excellent paper once read before the Photographic Society of Scotland, a writer once well remarked on this subject, "Loose talk about art has never been a very scarce commodity, I am afraid; but it has certainly always been a mischievous one." There has been talk enough about the mysteries of art, and no lack of rhapsodies on aesthetics and the poetry of pictorial expression; but no systematic teaching of what may be termed the mechanical bases on which pictorial effect must be built. Poetry there is in art, and mystery also; but it is little use prating of these to one who has not learned its alphabet. Instinctive perception of fitness and proportion will sometimes materially aid the artist in producing pictures, no matter what the tools by which they are produced; but no steady or progressive success can be hoped for that is not based on knowledge. The grammar of art must be learned before the student can expect to succeed in composition.

We wish here to speak very soberly; let us not be misunderstood in thus speaking of art and of its application to photography. We here make no extravagant claims for photography. We know well how necessarily limited is its range compared to painting; but we also know, within its range, how perfect are its delineations when guided by the trained hand and cultivated brain. We know its power in pictorial expression from the many wondrously beautiful things it has given to the world; and we feel assured that when a sound knowledge of art principles shall be more extensively applied, its powers will be developed, producing still more varied forms of beauty. Nor do we overrate what of art can be taught. Much of art which can be acquired by study

cannot well be taught in books. Yet much may be taught by explanation of rules and elementary principles, and by examples of the application of these rules and principles.

This is what we propose to do for our readers. Some years ago a very excellent series of papers on composition and chiaroscuro, by Mr. Lake Price, appeared in these pages. Admirable, so far as they went, we have since discovered that, for many photographers, they scarcely went far enough, lacking something of the photographic application necessary to give lessons their full value to photographic students. The material for a more extensive series of lessons, and of more especially photographic suggestion, has been for some time in preparation, contributions and suggestions for such a series having been offered by various of the ablest exponents of the art capacity of photography. Feeling that these lessons would acquire much additional value by being re-cast throughout by a gentleman whose education as a painter, and whose reputation and successful practice as an art photographer, would give weight and authority to his teachings, and by the original suggestion which such practice brings with it, we have induced Mr. H. P. Robinson to undertake the task of preparing the series of papers on art which we have for some time promised our readers. He will take the accumulated materials from published and unpublished sources, and, bringing to bear his extensive practical knowledge of what belonging to pictorial effect is possible in photography, and how it may be best compassed, we believe we can promise our readers that which has been so long a desideratum—an essentially practical series of lessons in art as applicable in photography. The series will be illustrated by examples, selected either from the works of painters or photographers, and will be produced by wood-engraving, photo-engraving, or any other process which shall be found best fitted for illustrating the purpose immediately in hand. The lessons will be commenced in our next.

#### FARADAY AS A DISCOVERER.

On Friday evening last, Dr. Tyndall delivered the first of two lectures upon the above subject to a very crowded and distinguished audience, at the Royal Institution in Albemarle Street. From the position occupied by Dr. Tyndall as brother professor at the Institution, and from his very intimate connection with Faraday during the later years of that philosopher's life, no better or more suitable lecturer could have been chosen to do justice to the subject.

The learned doctor prefaced his remarks by stating that, as the memoir he had prepared was a somewhat lengthy one, and it would be impossible for him to read the whole of it in the two hours allotted to him for the task, he should be compelled to omit some considerable portion of it; the whole would, however, be printed and placed in the hands of the members in a short time.

On Faraday's parentage the lecturer touched but slightly, merely mentioning that he was decidedly of Carlyle's opinion that a really able man was never born of stupid parents. He told the story of Faraday's apprenticeship to a book-binder, of his attending the lectures at the Royal Institution, of his making notes of these lectures and sending them to Sir Humphrey Davy, requesting employment in the laboratory of the Institution, of his engagement by Sir Humphrey, and subsequent promotion to be assistant in the laboratory; of his constant and unwearied investigations into the science of electricity, ending, in 1831, in his wonderful discovery that an electric spark could be produced from a magnet.

In later years, when Faraday had arrived at the zenith of his fame, when he had followed up one discovery by another, and had achieved a series of the most glorious successes, the great man still liked to look back upon his earlier life, and delighted to visit the little workshop where, once upon a time, he toiled as a poor bookbinder's apprentice. Although naturally of a sweet and gentle disposition, Faraday's character was by no means of a quiet and inexcitable nature,

for his mind sometimes displayed an extraordinary amount of fire and energy, qualifications which were put to good use in the prosecution and elaboration of his laborious researches. After his triumphant discovery of the possibility of deriving electricity from magnetism,—a discovery at present applied to many of our telegraph systems and to the production of the electric light,—Faraday turned his attention to the voltaic pile, and commenced a series of investigations producing results the novelty and unexpected character of which excited great interest in the scientific world; pursuing his studies further, he sought to simplify the terms and symbols used in connection with electricity, and to lay down the theories deduced from his numerous experiments. Turning next to the subject of gravitation and cohesion, he occupied himself with investigating and following up the ideas of Newton, and in this branch of science he was not less successful in arriving at important results than heretofore. In the year 1840 Faraday's health, which for many years had not been good, broke down completely, and he was compelled to seek relaxation from his labours in a visit to Switzerland; in that country he resided for several months, and his diary kept during that period shows how pleasantly he passed his time, and how delighted the great yet simple philosopher felt when surrounded by the grandeur of the Alps. The results of the researches undertaken by Faraday on his return to England will form the subject of the lecture this (Friday) evening.

#### CYANIDE OF SILVER IN COLLODION.

MR. BELL, Photographer to the Army Medical Museum in the United States, communicates to our contemporary, the *Philadelphia Photographer*, his plan of using cyanide of silver to collodion for the double purpose of preserving it and preventing pinholes in the negatives, having used it long enough, he states, to be certain of its value for the purposes indicated. His method of working is as follows:—  
“Dissolve in 2 ounces of water 100 grains of cyanide of potassium; add to it a solution of nitrate of silver, 50 grains strong, until precipitation ceases; pour the precipitate into a filter, and wash well with water by percolation. Dry and bottle for use.

##### COLLODION.

Ether	...	...	...	16 ounces
Alcohol	...	...	...	16 "
Iodide of ammonium	...	...	...	160 grains
Bromide of sodium	...	...	...	64 "
Cyanide of silver	...	...	...	5 "
Gun-cotton (Pary's)	...	...	...	192 "

##### MODE OF PREPARATION—No. 1.

Take 8 ounces of the alcohol, dissolve in it 60 grains of the iodide of ammonium, add the cotton, shake well, then add the 16 ounces of ether, and shake until all are dissolved.

##### No. 2.

“Into a mortar put the 64 grains of bromide of sodium, adding just enough water to dissolve it; then put in the 5 grains of cyanide of silver, granulate well together; add the 100 grains of iodide of ammonium, granulate, and finally add the 8 ounces of alcohol, granulate for ten minutes, then filter the solution into No. 1.

##### NITRATE BATH.

“Forty grains of silver to the ounce, acidulated with nitric acid.

“The developer I prefer is Anthony's, with a little modification:—

Water	...	...	...	52 ounces
Protosulphate of iron	...	...	...	3 "

Dissolve and add, drop by drop, a 10-grain solution of tannin in alcohol, until the iron solution is quite blue now add acetic acid 3 ounces, and 1 ounce of the gelatine syrup, and copper solution. Filter, and it is ready for use.”

Should the nitrate bath be old, the acetic acid must be increased until the developer flows smoothly. With a fresh nitrate bath make no change, as it is all one could wish.

#### GELATINE, SYRUP, AND COPPER SOLUTION.

Water	...	...	...	8 ounces
Gelatine	...	...	...	16 grains
Golden syrup	...	...	...	1 ounce.

Dissolve by heat, then add 1 ounce of acetic acid; saturate the whole with oxide of copper, made by precipitating a solution of nitrate of copper with a solution of caustic potash, washing and drying the precipitate."

#### A SIMPLE METHOD OF DOUBLE PRINTING.

BY WALTER WOODBURY.

SINCE attention has been called to the fact that very fine composition pictures may be obtained on card negatives, by the beautiful pictures lately produced by Mr. Edge, of Preston, allow me to lay before your readers a plan which I adopted some years ago, in Java, for producing the same result, by which very good effects may be obtained.

The negative of the figure, with the leaves, stones, or whatever may be used to form the foreground, should have the background carefully filled in with an opaque black; and from the negative in this state a transparency must be printed on a thin film of mica, by any known dry process, which may be done by damping the mica and placing it on a sheet of glass and preparing it as in the ordinary way, but giving such an exposure and development as will give a very strong black image, which may be gone over without much care, with an opaque material. The negative is then printed, giving, of course, a perfectly white ground. The talc mask may then be carefully placed so as to cover exactly the part already exposed, and the background negative then printed in; if this is carefully done it is impossible to detect any joint in the composition. The background should be lightly printed from a weak negative, but full of half-tone, and may in some cases be improved by allowing the light to fall on it after removal of the negative.

#### VISITS TO NOTEWORTHY STUDIOS.

WE have often endeavoured to impress upon our readers our conviction that success in photography depended rather upon the man than the method of working; upon the amount of knowledge and culture possessed by the photographer, rather than upon the process he selected or the material appliances he employed. Nevertheless, it may be safely affirmed, as a pendant to the first proposition, that the method selected "oft proclaims the man;" being, as it is, the result of his knowledge and culture. An acquaintance with the methods employed by eminent photographers is, then, of the utmost value, not simply as instruction, but as instruction commended by the prestige of success, and as example possessing the stamp of authority.

We propose, therefore, to bring before our readers a series of papers on the mode of working employed by men who have distinguished themselves in various branches of our art-science, either by their artistic, scientific, mechanical, or commercial success. We shall describe their studios, their processes, and their operations; their modes of working, the places in which they work, and the results they produce. We have already accumulated much material for these sketches, and shall avail ourselves of every opportunity of visiting noteworthy studios in which we may find matter of instruction or interest for our readers. And as we have the good fortune to possess the acquaintance or friendship of the majority of the most able and the most successful photographers, a class we have ever found least reticent and most ready to communicate the results of their experience for the benefit of their brethren or the advancement of the art, our

readers may rely on obtaining in this series of papers a faithful epitome of the practice of those who, by excellence, have acquired distinction and success, and an indication of at least the material elements which have conduced to that success. Turning in a direction in which public interest has travelled much during the last few months, we shall commence with

#### THE STUDIO OF M. ADAM-SALOMON.

M. Salomon's studio is pleasantly situated at Passy, a suburb of Paris, in the neighbourhood of the *Bois de Boulogne*. After an agreeable drive through the *Champs Elysées*, passing under the *Arc de Triomphe*, and trending to the left, we reach the *Rue de la Faisanderie*, and enter the pretty *Maison de Campagne*, or villa residence, where M. Salomon resides and produces those wonderful portraits which for many months past have excited so much admiration, so much envy, and so much discussion amongst photographers, and have won such high encomiums for the art and the artist amongst people of culture outside of photography.

On entering, we find no pretentious display of specimens in various styles and sizes, but, in a very pleasant little salon distinguished by elegance and taste in every appointment, a dozen or two examples of the one size and style of portraits to which M. Salomon devotes himself. These are not spread about or hung up, but are quietly piled in two or three heaps on a side table. The size of the portraits is 10½ inches by 8½ inches. Each portrait is placed under glass, and bound round the edge with a narrow slip of white paper; but none are upon mounts having any margin whatever. There are no coloured photographs exhibited, and very few persons, we apprehend, would dream of applying colour to the admirable examples of photography before us, which seem, indeed, the very perfection of monochrome portraiture.

Passing out into the garden, and neglecting for the present the sculptural atelier, we find the most recently erected photographic studio, which was used in summer, but is now abandoned for the old studio in which the majority of the pictures at the Exhibition were produced. The summer studio, as we may designate it for distinction, has been not inaptly described as simply a shed, with a glazed lean-to roof, facing south. But it is to be noted that there is not an inch of clear white glass in any portion of the studio. Immediately over the head of the sitter is a row of panes of dark blue glass, and all the rest of the glass is stippled with white paint to produce the effect of ground glass. As, at the time of our first visit, his studio was not erected, and at the time of our last visit abandoned, we cannot give any detailed account of the management of light in it. From the even flood of subdued light which entered the room when we saw it, we should have imagined it difficult to secure vigorous contrasts of light and shade and the fine relief and modelling which characterize M. Salomon's pictures generally; but as one of the finest examples of his portraiture which we have seen—we refer to the portrait of Dr. Diamond, which we exhibited in Conduit Street—was produced in this studio, we conclude that the artist finds means to govern the light to produce the result he requires.

We may remark, before mounting into the other studio, that in the garden is a canopy, underneath which is a background placed; and, we learn on inquiry, that on occasions when extremely short exposure is required, or when, from the lateness of the hour and the badness of the light, operating in the glass-room is impossible, and the production of a portrait is very important, M. Salomon operates in the open air. One of the results which we saw, taken very late in the afternoon of an October day—the sitter being a gentleman who left for India the same evening—was in many respects a very fine portrait.

We now mount to the studio in which M. Salomon usually operates. It is a rectangular room about 26 feet long by 16 feet wide, with a ridge roof about 13 feet high at the ridge, and from 7½ to 8 feet high at the eaves. Both

ends and the south sides and roof are opaque, the north side only open to a fine expanse of light. At the north side the roof is of glass throughout, but the whole of the skylight is stippled in imitation of ground glass. This skylight of obscured glass is, from ridge to eaves, nearly 10 feet in depth, and in length about 26 feet; consisting in length of 16 panes of 18 inches wide, and in depth of 4 panes about 30 inches long. At the north side, about 6 feet at each end of which is opaque, the light extends 12 feet laterally, and is a little more than 6 feet deep, reaching from the eaves to within 18 inches of the floor. It consists laterally of 8 panes 18 inches wide, and in depth of 2 panes

36 inches long. Thus it will be seen that the total amount of clear glass in the studio is 72 superficial feet. Curtains sliding on a rod at each end serve to contract, at will, the amount of the side-light, and also to modify its direction more or less in advance of the sitter.

The design subjoined, which we draw from memory, gives a view of the interior of the studio, showing the disposition of the light, and the relations of the camera and background to it. Some points of detail, &c., are omitted, to avoid confusion in the general presentation of the interior.

As we have said, the room is about 16 feet wide; but the operations are chiefly confined to the 10 feet of space

nearest the window, 5 or 6 feet of the width being occupied by a chair, tables, and other accessories of varied and excellent design. The floor is covered with a somewhat dark felt carpet, and the walls with the same material, which give an effect of extreme warmth and cosiness, especially pleasant in winter weather. Although M. Salomon can operate at either end of the room in his usual practice, the camera is placed in the north-east corner, whilst the position of the sitter is somewhat in a diagonal direction, and at a further distance than the camera from the side-light.

We must reserve an account of M. Salomon's mode of working for our next; but before concluding a brief description of the material appliances, we must refer to certain mechanical conveniences in the accessories, upon which, although trifling in themselves, much of artistic success depends.

The use of a column has been in this country so often absurdly misapplied that many of our best artists have discarded it altogether as an unnecessary conventionality. One of the common enormities in using the column has been the Procrustean practice of many photographers. The same column was used alike for short and tall models: a short man leaning against the base of a column, with his elbow raised higher than his shoulder; whilst a tall man leaning his elbow on the same base was compelled to stoop awkwardly, in order to find a resting-place.

M. Salomon uses the column, and often very effectively;

but he provides for the difficulty we have indicated. The plinth of the column is moveable, and can be elevated by means of an Archimedean screw like a camera-stand, so that the cornice of the plinth, upon which the model usually leans, can be placed at any height which convenience or pictorial conditions may require. In like manner the table, which often forms an accessory in sitting portraits, is provided with a similar means of elevation, and is readily accommodated to the height required by the sitter.

For standing portraits of ladies a convenient rest is employed, which we have not seen before. It consists of a piece of wood about a foot wide and three feet long, upon which the lady is invited to stand, and rest the back against a narrow upright piece of wood which is fixed in the centre of the baseboard, and kept firm by a strut extending between the top of the upright and the hinder portion of the baseboard. Great firmness and comfort are obtained by this simple body-rest; and which, supplemented by the head-rest, generally secures steadiness in the model.

M. Salomon appears in all things to require the utmost mobility and ready applicability—we had almost said, plasticity—in his accessories. Everything must accommodate itself to the position of the sitter, instead of the sitter accommodating himself to rigid and immovable appliances. The curtain is not, as is usual, attached to a fixture. On a cross-piece, attached to a rod placed in the base of a head-rest, the curtain slides on rings, and is

readily lifted about to accommodate the position in any part of the room of the sitter, or to occupy any required relation to the background, which is also not only movable, but is constantly moved to produce varied effects of light and shade in the picture. The canopy over the head of the sitter is in like manner readily movable, and when the sitter is once placed in position, he is no further worried with experimental changes to suit the light or existing arrangements. The position of curtains, light, background, tables, chairs, column, or camera—all, or any—are quickly changed if required, to suit the model and produce the pictorial effect which the artist has conceived.

In our next we shall describe M. Salomon's mode of operating: his mode of arranging the light and managing his sitters. In the meantime we conclude our account of appliances by quoting some details from a description\* by our friend, Mr. Pollock, an American photographer, who passed some time in M. Salomon's studio during a visit to Europe.

"The lens used was a double combination portrait, by Hermagis, carefully selected, after trial, from six others by the same maker; no diaphragm was used, and in three sittings exposures varied from eighteen to thirty seconds, according to strength of light. The collodion film, previous to development, appeared semi-opaque, creamy, neither very thick nor thin, indicating a full proportion of iodizing, with probably a liberal supply of bromide. The developer acted slowly, considering length of exposure, but brought out a full, dense image, requiring but little intensification, which latter was secured by the addition of a modicum of silver to the developer, and applied, in one case, before washing or fixing; in another, after both operations were concluded. The plates were not fixed in a bath, but held in the hand while a solution of cyanide was poured over them, which acted with energy, cleaning off everything like tendency to deposit on the shadows. The result in each case was a negative yielding prints without retouching, with the characteristic brilliancy of those issuing from this establishment; a marked feature of all M. Salomon's work, visible alike in negatives and prints, being the granulated, flesh-like texture of the skin, closely resembling fine india-ink stippling."

## PHOTOGRAPHY AS A PROFESSION.

BY S. THOMPSON.

A MAN'S productions in art, or photography, are the cumulative result of his *whole* culture. Their excellence—if they possess it—is the joint result of natural artistic capability and careful cultivation. It is idle to pretend to *coach* him up in art-knowledge by means of any number of discursive lectures, labelled, "On Taste," "On Feeling," &c., &c. There are no "short cuts" to art-knowledge any more than to other fields of human learning. Once, and for all, that fact may be accepted as an axiom. He must possess the artistic faculty or temperament, emphatically, to begin with, for the want of which nothing can compensate, and then it must be fostered and developed by a lifetime of untiring study; much of it in the *form of careful, thoughtful observation*. The best lessons are often, not those the teacher gives, but those the pupil learns. Such an one is always learning, even unto the end of his career. Every picture he looks at, every shop-window he passes, all he reads, all he sees, that is practical, helps to feed the sacred fire. This long education of the eye—the chief portal through which art-knowledge enters—combined with the artistic nature, at length results in that cultivated art-power we call, in all-confusing terms, *taste, feeling*, and I know not what besides, but which includes them all.

The same in kind, with every artist, though widely differing in degree and in its manifestations, it guides him in the *instinctive* rejection or acceptance of what is good or bad in his work, and is always ready, and always at hand, and is,

in short, *himself*: a finely-polished edge, like a Damascus blade that severs the Gordian knot of difficulty in the endless combinations of circumstance that come before him in his daily practice.

At once above and beyond rules, though not despising them—for rules are for our aid and guidance, not for our abject bondage—he is not fettered by them, but gets above them by outgrowing them, even as musicians often forget their notes by name, and authors the rules of grammar except in practice. Weaker men get entangled and lose themselves in petty theories about parallel lines, and a great deal more; get little rules by heart, that serve them as a straitjacket would. Thus "clinging to some ancient saw," or "mastered by some modern term," the result of culture founded on a basis so narrow is often something that perhaps has no glaring faults, but, somehow or other, is not a picture.

In such a spirit Gainsborough painted his famous "Blue Boy," in half playful, half contemptuous disproof of a dictum of Reynolds, that "the masses of light in a picture should be always of a warm, mellow colour, and that the blue or green colours should be kept almost entirely out of the masses." Gainsborough's instinct kicked at such rules. He felt that every great painter makes his own laws of colour; so here he chose to show that whether blue should tell in the principal light or not, depended on *how* the blue is used; and by mellowing and breaking the tint, as Mr. Leslie has pointed out, has succeeded perfectly. Still, Sir Joshua's is a sound general rule. But rules in *art* are not intended to be straitjackets.

A want of art-knowledge among photographers has now come to be an admitted fact; but it is much to be feared that it is not the means of culture that are so much wanted. They often lie at the very door; and there is a musty adage that says, "The tools will always come to the hand that can handle them." All that books can teach may be found in those pointed out by Mr. Mudd in the YEAR-BOOK. It is very much to be feared that a want of that natural bias towards art in so large a number of those who have taken up the practice of photography is at the bottom of it. Many are now beginning to discern in themselves a want of something, they scarce know what, but by reason of which they have not advanced in excellence beyond the standard they reached some years ago, and eagerly run after anyone who assumes to teach or coach them up, and are swayed backward and forward by any pretender who offers a course of his *clair vitæ* that is to do the business. This invariably ends, as it must do, in disappointment and desertion to some fresh teacher, again ending in disappointment, blank puzzled faces, spherical aberration of ideas, and universal fog!

Nor can it be alone ascribed to the undoubted fact that the majority were originally designed for altogether different pursuits. It is an equally indisputable fact that many of our most distinguished painters, past and present, including some of the most eminent of the R.A.'s, began life in other trades and professions, some of them in the humblest possible callings. But all of them had an irresistible bias towards art, which made them gravitate to it as naturally as water finds its level. It is also well known that a large number of photographers have entered the lists, attracted by the fact that photography was a very profitable pursuit, and, without deliberating about whether their own abilities lay in that direction, took it up in a purely commercial spirit. On the other hand, whoever heard of a painter who became such influenced only by the same reasons? The hope of making a respectable living, and the chance of something more, may have had its due weight, but the same end might be attained in countless other pursuits. No; they became painters because they could not help it, nor strangle their impulses, even as the poet sings because "he cannot choose but sing." It is no disparagement to a man to say that he may have excellent abilities, and many gifts, but not those which peculiarly fit him for this pursuit. Did he ever ask himself seriously if he had in him the raw material which might be

\* In a letter in the *Philadelphia Photographer*.

manufactured into artistic stuff: that question of questions, of more vital importance to himself than anyone else? If he has mistaken his vocation, photography is not responsible. Better for himself and his own future that he should seek "fresh fields and pastures new" now.

Dissentients may perhaps triumphantly instance men of this class who have succeeded. Perfectly true; but the day has now gone by, and we are entering upon another era in photography.

That there will always be a steady demand for an average—if fluctuating—amount of good work is as certain and indisputable as the fact upon which it is based, viz., that photography is altogether unrivalled in some of its aspects and capabilities. But during the carte-de-visite campaign, the art, in military parlance, was put upon a war footing, and a much larger number entered than can be maintained on the establishment in time of peace, much less in time of universal depression.

There is a fatal facility in photography by which one may reach a certain standard. Beyond that it is not so easy. As soon as this standard is carried still further, which it undoubtedly will be, and the goal becomes more difficult of achievement, so will the competitors in the race fall off; and it follows as a natural sequence that the practice of the art becomes more profitable to those who can raise themselves to the lofty argument. While the standard is a low one, the remuneration will be a low one, because the competitors who can reach it will be so numerous. Does this inflict any hardships upon anyone? No; as soon as photography has reached a greater altitude on that mount

"Where Fame's proud temple shines afar,"

men will cease to enter it so readily, but will ask themselves as thoughtfully as if they were proposing to themselves a career which might possibly end in an R.A.'s diploma, whether they have the special talents and bias for success in an art-science like photography.

The ultimatum of what can be attained in art by photographic means is certainly not yet arrived at, nor can be with safety predicted. Some extensive art-fields are at present limited only by the cost of duplicates. In all other modes of multiplying pictorial matter for trade, book, and other purposes, from stone, wood-block, steel-plate, or other mediums, though the artist's work costs incomparably more, the duplicates cost very much less. Thus, when very large numbers are to be produced, publishers and others resort to the above means. Whenever the production of duplicates at all approximating to those from stone or wood in cost is made possible, a price which now seems fabulous can be afforded, and would be willingly given by publishers for original or special negatives by first-rate men.

Far be it from my purpose to discourage the aspirant after art-knowledge, while endeavouring to point out how broad and wide and beautiful a thing it is, and to caution him against the fallacy of "short cuts" and injudicious teaching. That knowledge, though it will never compensate for the want of the artistic nature, will, to some extent, enable him to conceal it. In closing that series of masterly articles in the *Times* on the pictures at the Great Exhibition 1862, their author (Tom Taylor) says that the more he saw and thought about art, the more diffident he became, and that "reference from art to nature is not enough. There is nothing more difficult than to see and know nature. To tell the bulk of people that they may trust to their notions of nature for their judgment of art is simply to mislead them. It requires the labour of a life to apply this standard." Still, he commends the study, and says that while pursuing it, it is hard indeed if we do not gain a stronger sense of that persistent life with which art clothes itself so variously, pursues so many tracks, manifests itself in such various countries, and at times so different from each other, and yet is still art—the adornment of life, the glorifier of use, the dispenser among the labours of men of that beauty which God has everywhere stamped upon the face of His creation.

## ENNEL'S HINTS.

This being the time for paying Christmas accounts, I am reminded that I owe you various items, and I now hasten, after a long delay, to discharge my obligations.

In the first place, I owe you thanks for the kindly spirit in which you invariably receive my communications. I am actuated by a desire to disseminate among our brotherhood of the "light-art science," (I object to the hackneyed and current term "black art,") whatever may be, to the best of my knowledge and belief, useful to them. You meet me in a kindred spirit, and I thank you for it.

Secondly, I owe you an answer to your comments upon my last (p. 570); and thirdly, I owe you a grudge for having misinterpreted the meaning of some points in the same.

How such a debt as the third can be satisfactorily settled may be a question for *Punch*, or metaphysicians, to decide; but you will, perhaps, help me out of my difficulty by owing me a grudge for entering into a sort of controversy with you. We shall be quits then.

To return to your commentary. How, and where, have I mistaken the *purpose* for which certain modes of obscuring the glass is recommended"? Believe me, I know the purpose, and I have never, directly or indirectly, denied it. But you will admit that light is not every day alike, nor at every part of the day. On this axiom my proposition is founded:—"Put not a permanent obscurer against an occasional intruder."\* You yourself suggest blinds of tracing cloth, or double sashes, evidently preferring movable to permanent obscurers, and I am glad we agree. I am also of your opinion that Venetian blinds and calico are too dense in many cases. I never recommended them, as would appear from your remarks, but "light, white blinds, on the Venetian-blind principle," i.e., wide flys of (say) tracing cloth on light frames instead of narrow wooden bars. Our climate is such that frequently we cannot afford to lose even that little light which starch obstructs. A movable thin screen is therefore the best of the two. I enclose a sample of starched "book muslin." Photometrically it is far less dense than the accompanying tracing cloth. Manufacturers of the latter would do well to treat muslin stuffs in the way of their tracing cloth for photographic purposes.

To tell truth, the greatest majority of photographers, though they talk a great deal about light and lighting, yet grope in the dark in this respect. They are mostly "shade blind," to use a term analogous to *colour blind*. They cannot appreciate a delicate *shade*, technically *half tones*, in a sitter's face, but a downright dark shadow. The clumsy means to which they have recourse in trying to attain at a desired effect are truly ridiculous. Not to speak of the mechanical means, they seek it in collodion, developer, and intensifier, according to this or that advertisement, and, these helps failing, as of course they must, if the lighting is wrong, they at last believe it. And now how to set about it is the question. Well, A. Salomon produces good effects; *ergo*, they say, we must adopt his mode of lighting. He has a frosted skylight; therefore, we must have it too. Verily, I say, his skylight requires something additional—chiefly judgment. And we must not forget that our climate is not that of Paris. Slavishly following a given example through thick and thin is neither art nor science. What is wanted is a practised eye, and judgment to select appropriate appliances to suit particular circumstances.

Have I allowed myself to be carried away? Well, snip away with your editorial scissors as much as you please.

\* Our correspondent still regards the use of starch as intended to keep out an occasional intruder, and implies that because the intensity of light is constantly varying, a constant veil of any obscuring material is an error. But the relation between clear glass and obscured glass does not vary, and some photographers prefer as much pure light as they can get through clear glass for direct and principal lights, and a relatively equal proportion of softened or subdued light for illuminating the shadowed parts slightly, and so producing harmony, and avoiding black opaque shadows. No matter what the condition of the light, the relation between that through clear glass and that through obscured glass will be much the same. For shutting out occasional direct sunlight, moveable blinds are doubtless best. The book muslin enclosed would probably be very useful.—Ed.

Allow me to make another observation. In your article aforesaid, you speak of the slope of the roof as if I had mooted that question. I only spoke of this or that inclination—i. e., flat roof, ridge-roof, &c.—as the context will show. The same as regards the height of the roof. It was the height of roof, *per se*, particularly in relation to Mr. Blanchard's observation at page 525, to which I referred. Mr. Blanchard wields the pen of a ready writer: let him, *pro bono publico*, explain his meaning.

I will turn to another subject. On reading J. Q. A. Tresize's article on Stereographs, quoted by you, p. 588, December 6th, 1867, from the *Philadelphia Photographer*, a thought momentarily struck me that, after all, the numerous "hints" which are scattered broadcast in your valuable *Journal*, are, in a majority of cases, only thrown away. In that article the old mode of transposing stereoscopic prints is still prescribed; whereas my *modus operandi*, as exhibited last year at a meeting of the South London, was quoted fully in the very same *Philadelphia Journal*. But, on the other hand, I know that some photographers have adopted my plan here, on the Continent, and in America, so I may rest and be thankful.

In endorsing almost every word of my esteemed friend, Mr. J. Hughes, read by him at the late meeting of the London Photographic Society, I would nevertheless pick a hole, a very small one, in one remark of his. "When a man calculates closely . . . how many cartes he can get out of a sheet . . . such a man is sure not to succeed, for he ignores all the other elements," &c., &c. In the face of this remark I am not ashamed to own that I do always get forty cartes out of a sheet instead of thirty-two (gaining 25 per cent.—how tradesmanlike!), and every one whom I have shown the method thanked me for it. I cannot see, for the life of me, how thereby "all the other elements are ignored." I have heard many a one state as an axiom, that there must be no economy in photography. Why? If they mean it in the sense of stinginess, I agree with them. But then it applies equally to all transactions of a rational being.

Perhaps some of your readers may wish to know how I cut out ten cartes from a quarter sheet. Well, here is the plan:—By a flat, parallel gauge,  $2\frac{1}{2}$  inches wide, cut off longitudinally two strips; each yields three cartes. The remainder may be used for two cabinets or four cartes. Faulty bits I use up for chess problem papers.

Being on the subject of the depressed state of photography, I agree with your view of the case, viz., that the late money crisis has a great deal to do with it. Nearly every trade or profession tells the same tale, and the Government returns of this month would seem to point in the same direction.

ERRATA.—Page 574, second column, line 2, for "continued" read "continuous"; line 23 from top, read "Venetian-blind principle"; line 19 from bottom, read "45°" for "50°."

## Correspondence.

### HYPOSULPHITE OF AMMONIA FOR FIXING.

DEAR SIR,—I am indebted to you for calling my attention to the short editorial article that appeared in the *PHOTOGRAPHIC NEWS* of 10th May last, in which you reported the use of hyposulphite of ammonia as a fixing salt by Mr. T. H. Redin, Governor of Carlisle Gaol; and at the same time mentioned the circumstance that, if further trial should establish its superiority over the soda-salt, a method of preparation devised by Mr. Losh was available by means of which it could be cheaply manufactured.

Since reading my paper "On the Hyposulphites" at the Photographic Society I have gained more experience respecting the preparation and properties of the ammonia-salt, and find that it is very soluble in water, somewhat difficult to crystallize, and that the crystals are deliquescent.

I have not yet definitely determined what form the hyposulphite of ammonia takes; whether, according to Sir John Herschel, it crystallizes in small needles, or, as Rammelsberg states, in rhombic laminae?\*

Here is an interesting allusion to the hyposulphite of ammonia, and to its property of dissolving the chloride of silver. I quote from an early chemical treatise, by Colin Mackenzie, entitled "One Thousand Experiments in Chemistry," fifth edition, dated 1825.

"EXP. CCCVIII.

### "ACTION OF HYPOSULPHITE OF AMMONIA ON MURIATE OF SILVER."

"When hyposulphite of ammonia is poured on muriate of silver, it dissolves it; and if into the saturated solution alcohol be poured, a white salt is precipitated, which must be strongly expressed between blotting-paper, and dried in vacuo. It is very readily soluble in water, and is extremely sweet to the taste. Its sweetness is unmixed with any other flavour, and so intense as to cause pain in the throat. One grain of this salt communicates a perceptible sweetness to 32,000 grains (i. e., nearly half-a-gallon) of water. If the alcoholic liquid be evaporated, thin, lengthened hexangular plates are sometimes formed, which are not altered by keeping."

The writer was evidently acquainted with the pure hyposulphite of silver, and its proneness to decomposition, for he appends to the above the following observation:—

"When the hyposulphite of ammonia refuses to dissolve more muriate of silver, if an additional quantity be added, it is rapidly converted into a white crystallized powder. It is extremely insoluble in water, but readily and abundantly in ammonia, forming an intensely sweet solution, from which an acid precipitates it unaltered, even when copiously diluted. Dried in vacuo, and kept in a closely stopped vessel, it blackens and undergoes spontaneous decomposition. The phial, whenever opened, is found full of sulphurous acid; and when (the decomposed substance is) washed with ammonia, a considerable residue of sulphuret of silver is left. Heat effects the same change at once."

Modern chemistry seems to have added but little to the information here given, beyond supplying the analytical proofs of the several decompositions here mentioned.—I remain, dear sir, yours truly,

JOHN SPILLER.

Woolwich, January 18th, 1868.

### INDIA-RUBBER FOR MOUNTING.—DISTILLED WATER.

DEAR SIR,—In discussing the durability of india-rubber cement for mounting, it seems not to have been remarked that the pure rubber is much less liable to oxidize into a resinous powder than gutta-percha, or even than many of the varieties of mineralized rubber. You must have noticed that both gutta-percha and some sorts of elastic rings, after being put away for some time, are found quite brittle, and sometimes of the consistency and elasticity of cheese-rind; but do you recollect anything of the kind happening to the pieces of bottle-rubber, or even to the manufactured squares used for erasing pencil-marks. Such pieces are occasionally found in desks or drawers where they have been lying for years, and in their original good condition. I have an old pattern-book, manufactured in 1855, with a rather thick solution of rubber round the edges only of the prints. They are now quite firm, and not easily removed without tearing. No doubt the prints which have been referred to as separating from the mounts—sometimes in a day or two—had too thin a coating. I have lately tried the solution sold for Swan's carbon process. It answers very well if three or four coats are given to the print, and one or two to the mount; but even then seems much thinner than what I used before. The dark colour of the cement shows a little in the pattern-book, and would be an objection to so thick a solution.

\* Gmelin's "Handbook of Chemistry," Vol. II., p. 454.

With regard to the protection afforded by india-rubber against injurious substances in the mounting-board or paper, it seems to be forgotten that, except in the case of single and framed prints, the face of one will usually be in close contact with the back of the neighbouring mount.

Whilst I am writing, let me confirm Mr. Cherrill's statement that for ordinary photographic operations distilled water is quite unnecessary. I have not used such a thing for upwards of ten years. For the negative bath the water requires purification with oxide of silver; but for all other purposes Thames or New River water will do, just as it comes from the tap.—Yours truly,  
RUSSELL SEDGFIELD.

[There is, doubtless, as we have before observed, great difference in samples of india-rubber; but we think we have seen the gradual deterioration by air and light of very good and pure samples; and the thinner the layer, of course, the more readily it becomes completely oxidized.—Ed.]

### THE DISCOVERY.

SIR,—Having heard that, by dint of study and perseverance, Mr. McLachlan had come across a valuable method of working, I read his letter in your last with delight. When, however, I studied over that portion which describes the large quantity of perfect negatives from so small an amount of silver, although not desiring to be sceptical, I felt that an immense boon would be given to the "cheap Jacks" were this found to be so.

I am at once an enemy to the race there has lately been for cheapness; I know, also, Mr. McLachlan is an enemy to the five shilling per dozen cut. I therefore think those who have kept up their prices are worthiest to be benefitted by Mr. McLachlan's generous offer; and it occurs to me that if Mr. McL. can devise some way of letting only the worthy into the secret, he will get as much credit for his skill and generosity, besides punishing the low lot, and will also do an act that will tend to raise the quality of photography in respectable places where, at times, difficulties occur.

I fancy I hear some of the "Jacks" cry out, "Selfish mortal!" My only answer is, that they have done all in their power to disgrace photography, and have erected barriers to the progress of cultivated taste in this department of the pictorial world which will take years to break down.—I am, yours,  
LITO.

### CARBONATE OF AMMONIA IN THE FIXING BATH.

SIR,—Allow me, who, by bitter experience, has acquired some right to speak, to protest against the use of carbonate of ammonia in the fixing bath.

Along with many others, I believe, I adopted it because recommended by many who I thought ought to know. But a variety of failures have driven me to give it up again. Yellow spots would form in the pictures for which I could find no cause, and those which had no spots turned yellow after a comparatively short time, especially if exposed to damp, or closely confined, which, perhaps, may explain some of the failures of varnished prints.

Increased precautions were tried with only a slight benefit. So, bothered and disappointed, I gave it up, and got pictures as good as those I used to have.

When using the ammonia, the bath (especially if used twice) had an unpleasant sulphur smell; but I think it was not the same as the addition of an acid causes.

I trust some of your correspondents will be able to throw some light on the subject.—Yours obliged,  
HYPO.

[We shall be very glad to receive accounts of the experience of our readers on this subject; but we must caution our present correspondent and others against the *post hoc propter hoc* form of argument. That it has happened that whilst using carbonate of ammonia he has also, from some cause which, without knowing more about the operations, we cannot explain, met with yellow spots, &c., we do not doubt;

but he might almost as well attribute extreme redness in his prints to the use of gold in his toning bath, as sulphuration and yellowness to the use of an alkaline fixing bath. The cause and the result he describes have no affinity.—Ed.]

### Talk in the Studio.

**PRESERVATIVE NITRATE OF SILVER.**—A new form of nitrate of silver, under the name of "Sel Clement, or Preservative Nitrate of Silver," has recently been introduced to our notice by Mr. C. E. Elliott, who states that it is a French production. It is especially intended for printing purposes, for which the prospectus states that it is equal, and in some things superior, to ordinary nitrate of silver, whilst it is much less in price, being only 2s. 9d. per ounce. The very unsatisfactory weather which has recently prevailed has prevented our undertaking comparative trials with it. A hasty examination shows that it has, as might be expected, a large portion of foreign matter, not nitrate of silver, mixed with it; but practice alone will determine whether, all things fairly considered, it is an economical article to use.

**TO STIPPLE THE GLASS AND SUBDUCE THE LIGHT.**—We are favoured with the following by a correspondent, who describes it as an excellent method—"Take patent dryers and add one part of boiled oil, two parts of turps, and a very small quantity of ordinary house decorator's varnish, which will give it a tacky nature, and will cause it to work much better: it must be much thinner than ordinary paint. The dryers are of a transparent nature, and if you want a greater body, add a little white lead. The white lead should not be used alone. Now for the way to work it: lay it on as even as you can with a painter's brush or tool; then let it remain a short time to let part of the spirits evaporate, and stipple it with a new pound-brush or dust-brush, and then, if you want a better finish, take a piece of cotton wool and cover it with a fine piece of muslin, and carefully press it all over."

### To Correspondents.

\* \* \* Correspondents will save some trouble and confusion by adopting signatures more specific and distinctive than "A Subscriber," "A Constant Subscriber," "A Constant Reader," &c.

**CONSTANT SUBSCRIBER.**—In producing stereoscopic transparencies in a copying-box you must use a pair of lenses, one for each half of the stereoscopic negative. Your attempt to copy both halves of the negative by means of one lens must necessarily be a failure in two ways: first, you will have difficulty, unless you use a very small stop indeed, in producing equal sharpness throughout; and, second, if you succeeded, the halves of the slide would require transposing after the transparency was produced. By using a pair of lenses both these difficulties will be removed: you will have no trouble in getting each picture of the pair properly defined; and each being reversed by the operation of copying, no transposition will subsequently be required. So far as the question of sharpness is concerned, by using the lens you mention you may get a sharp copy of a large size by employing a small stop, a condition generally necessary in copying.

**A SUBSCRIBER.**—We believe that a letter addressed to the gentleman in question, at Birmingham, will reach him, without more detailed address.

**W. S. (Cromer).**—We do not remember the price of a good book on coins, but will make some enquiry, and, if we ascertain, will let you know. You will obtain information by writing to J. R. Smith, Bookseller, Soho Square, who publishes works of that class.

**WASP.**—The *Philadelphia Photographer* can be obtained of Trubner, Paternoster Row.

**J. W. H. A.**—See answer above. You can order it and receive it monthly. 2. Tracing cloth or tracing linen is the best material we know. See "Ennel's Hints" in our present number. 3. Much depends on circumstances, and whether you can afford to stop out a considerable amount of light permanently; if not, blinds will answer best. 4. Stippled glass obstructs a large amount of light, but, with the studio you describe, the amount of side light would probably be sufficient at all times for your principal light, and the light from an obscured skylight probably be sufficient to illuminate the shadows and give harmony.

**IGNORANCE.**—Bee's-wax is not perfectly soluble in ether; but, by cutting into shreds and macerating, you will get a saturated solution. Benzole, or an essential oil, like that of lavender or rosemary, is a better solvent.

- TITUS WAY.**—There are various works on "Mesmerism," but in most of them there is a considerable mixture of imperfectly understood science, delusion, and humbug. That an occult natural power, designated "Animal Magnetism," exists, there can be little doubt; but the knowledge of it has not been reduced to a definite physical science, and what is known is largely mixed with quackery and charlatanism. Dr. Teste's "Manual of Animal Magnetism," published by Balliere, Regent Street, is a tolerably complete book on the subject. The "Zoist," which used to be issued periodically by the same publisher, is devoted to the subject.
2. There are a variety of modes of making ice in summer. You will find several recipes on page 395 of our last volume.
- D.**—We are not familiar with the art educational facilities to be obtained in Scotland, but it is tolerably certain that in Edinburgh and other large Scottish cities such facilities exist. In Edinburgh there is a Scottish Royal Academy. Should we be able to gain the information for you, we will give it on a future occasion.
- R. M.**—The silvery foggy deposit in your shadows is most probably due to the use of damp glass, and is most common in cold damp weather, when the coldness of the glass rapidly causes a deposit of the moisture on the atmosphere on the glass, even during the operation of coating the plate. It is generally under the film, and shows most at the back of the negative. Very slightly warm your glasses before coating the plate. Sometimes the use of impure acetic acid will cause a similar defect.
- F. M. YOUNG.**—The lenses you mention are the best for stereoscopic landscape work of any we know. You will not get any equal to them, we believe, at a less cost. 2. Mr. Mawdsley's method of alkaline development, described in the YEAR-BOOK, is applicable to any process in which alkaline development is suitable. 3. The especial claim of the gum process, as described by Mr. Gordon in the YEAR-BOOK, is the superior keeping qualities of the plates. We cannot, from personal experience, give you an estimate of the relative advantages of this process and the coffee process. We have had several private communications recently, speaking in very high terms of the latter, and thoroughly endorsing Mr. Joceelyn's statements. We hope for some further communication on the subject from that gentleman and from one or two others who have promised to state their experience in the matter.
- A SUBSCRIBER.**—Messrs. Marion & Co. publish a large number of photographs of the architecture of Spain. Mr. Thurston Thompson has recently taken a large number, also, for the Science and Art Department at South Kensington; whether they are yet published or not we are uncertain.
- II. W. (Croydon).**—Much depends on the thickness of the collodion you obtained. Many samples will work well without any further addition of alcohol. If, on trying, you find it too thick, then you may add (say) half the amount of iodizing solution indicated by the makers. If the collodion be not too thick, you will require a larger proportion of iodide, and also, for some purposes, of bromide, than you have added. For ordinary purposes, 4 grains of iodide of cadmium and 1 grain of bromide of cadmium (per ounce) will serve; for subjects having much contrast half a grain or a grain more bromide may be used. 2. Collodion bottles are better kept upright, so as to secure perfect subsidence of any residue. Those not in use should be carefully corked or stoppered and tied down. 3. We believe that both samples you name will answer for transparencies.
- W. J. A. G.**—We advised the use in a tunnel glass-room, with a sloping front light, of blinds sliding from side to side, for the following reason:—We should generally use the blind placed so as to cover something more than half the skylight, the sitter being under that portion; the portion uncovered to join the side-light uncovered forming a continuous high side-light. The plan you suggest also is good: by having two blinds on rollers, running from top to bottom, one might be kept down altogether to secure shadow, and the other as much withdrawn as you choose. This plan, in conjunction with the lateral sliding plan, would give great control over the light. The tunnel is not an evil *per se*; but the sloping front light, which used to be recommended in conjunction with it, is so, unless the studio be of large proportions; but the ridge-roof undoubtedly is simplest and most manageable. 2. We recommended fastening the cord to each ring to secure even running, but if you find fastening to the last ring answers, of course all is right. 3. We have not heard of pin-holes in the coffee process, but they are a frequent trouble in the tannin process, to which, in some respects, the coffee process is analogous. The use of a very dilute preliminary coating of albumen has been recommended as a preventive; but we are not partial to introducing plates so prepared into the nitrate bath. 4. In the coffee process, the addition of a very minute trace of citro-silver with the first application of the pyro developer is generally desirable, unless you use the alkaline developer. A fuller exposure would enable you to get out the image faintly with plain pyro. The question of sufficient exposure is altogether a relative one. As a rule, with alkaline development much shorter exposure is permissible. 5. With a large aperture, we have no doubt that the lens in question will give you instantaneous pictures in suitable light and of suitable subject; but it is not the most rapid stereo lens. 6. Small pictures will bear a much higher glaze than large ones: we agree with you in thinking an excessively high glaze for large pictures vulgar and inartistic. Hypo is the cause of the stains.
- OXONIENSIS.**—Something depends on the dimensions of such a room as to how far good results can be produced. If it be sufficiently large to permit suitable arrangement of blinds, good results may be obtained. Cover the skylight from top to bottom, for about two-thirds of the width, with white blinds on the south half, using the light from the north-west, inclining the sitter a little to the east, and working diagonally with the camera in the north-west corner. 2. Almost any dark carpet will answer if the tints are tolerably uniform without great acinic contrasts: browns are good colours. 3. Either of the tents you name are good, and they are very similar in character. We can scarcely say which is best. Thanks for your complimentary remarks on the YEAR-BOOK.
- W. B. A.**—There are several modes of enlargement, but the details of any of them are much too lengthy for insertion in our column of answers. You will find an account of a method of enlarging with the magnesium light in the present number; you will find in the latter end of our last volume, and also in our YEAR-BOOK, a description of a very simple method of enlargement. If you have the volumes of the NEWS you will find articles on producing enlarged negatives, and, also, on using the solar camera. If you have to begin your experience in enlarging and wish to utilize your present apparatus, you cannot do better than adopt the plan given in our YEAR-BOOK. With your quarter-plate lens and camera, and your whole-plate camera, you may easily improvise arrangements for enlarging cards to whole plates by the process described.
- A CONSTANT SUBSCRIBER (W. H.).**—The streaks may be due to various causes, but one of the most common is immersion of the plate whilst ether is still evaporating from the film, and the repulsion between this and the bath during the process of immersion causes streaks. The most certain remedy is moving the plate rapidly about both vertically immediately after immersion instead of allowing it to remain still a short time; also let the film set well. The lighting of the figure is pretty good.
- Q. Y.**—As you do not state which of the methods you have used for toning, or which of the methods of transferring we described, we cannot well suggest the cause of your failure. It would seem, from the failure you send us, that you have attempted to remove the film when dry. In using the dry method you will bear in mind that the paper and film both should be damped again before removing; also, that if the glass be treated in the first instance with wax, the transfer is more safely effected. In the question of toning there appear to be two or three errors. In the first place the image has been scarcely sufficiently clean and vigorous to commence with. There is a little deposit on the pure whites which should be avoided. A gelatino-iron developer would help you in this respect. Next, whichever system of toning you have adopted, you do not appear to have allowed it to permeate the film thoroughly, so as to be as perfectly at the side next the glass as on the upper surface. Should you fail after further trial write again, stating details of the process you pursue, and we then may be able to help you.
- B. MAGIC.**—A quarter-plate lens may be used for a magic lantern with advantage. You will find details and diagram in our eighth volume; also instructions in our last volume. 2. There are several processes for photographing on wood, all of which have been described in our pages. For what purpose do you require the operation? If for wood-engraving, you must use box-wood. The process with uranium and silver in collodion, described in our eighth volume, will answer well. You can use oxalate of silver for the process, or oleate of silver. If for ornamental purposes, a smooth white wood, like sycamore, answers well, and the collodio-chloride process is simplest.
- J. BULLOCK.**—We do not remember the communication to which you refer. We should think, however, that you would be able to get microscopic glass of Mr. How, Foster Lane.
- F. S. B. L.**—Although, as a general principle, we disapprove of front light, yet, in your case, we think that the portion of front light in No. 1 will at times be useful. As a rule, it should be covered with blinds; but in dull weather, and for some sitters, you will find it an advantage to be able to use it. Therefore, on the whole, we prefer No. 1, which will, we think, answer well.
- W. G. G.**—Crush a little of the slag, and digest with water or with hypo. The addition of sulphide of potassium will enable you to ascertain if any silver salt is present. Plumbago crucibles are not the best. Those known as London pots, of burnt clay, are the safest.
- II. S.**—Received, and shall have our attention.
- ENGINEER.**—The fault of which you speak is new to us. We will give attention to the matter, and answer in our next.
- II. B. (Bradford).**—Your question is scarcely sufficiently clear. You ask if the "color-taste" of alkaloids is infallible. Do you mean colour test? and infallible in relation to what?
- RECEIVED:** "Photographie Mosses for 1868." "The Art of Photographic Colouring," by David Rees." An important communication on Blisters in Albuminized Paper, some Reviews, and other articles are compelled to stand over for lack of space. Several Correspondents in our next.

### THE ELECTRIC LIGHT FOR PHOTOGRAPHY.

Mr. WOODBURY has recently superintended the arrangements of Disderi and Co. for producing gelatine reliefs for the photo-relievo printing process by the use of the electric light. The light is obtained by means of the Alliance Company's (French) electro-magnetic machine, which Mr. Woodbury considers has some important points of superiority over Wilde's electro-magnetic machine, inasmuch as a similar amount of light is obtained by a very much less amount of cost in wear and tear; the result being obtained in the French machine by 400 revolutions round several electro magnets, which in Wilde's is obtained by 3,000 revolutions round one electro-magnet. It will readily be seen, therefore, that the wear and tear is much less in the French machine than in one in which the exceedingly rapid rate of revolution involves much friction and frequent breakage. The cost of each machine (about £250) is about the same. The power is obtained at Disderi and Co.'s establishment by means of one of Lenoir's gas engines. The cost of gas is, of course, great; but there is the especial advantage that the power can be secured and dismissed without waiting or delay, so that no waste of fuel is involved. Mr. Woodbury estimates that the amount of gas burnt in obtaining the power would give a light nearly equal in amount to that obtained from the electro-magnetic machine; but, of course, the latter would be in a form less available for photographic purposes. The battery power necessary to secure a similar electric light would require about forty of Bunsen's cells. The cost in his present mode of working is one shilling per hour for gas, and about two-pence for carbon points. The time of exposure necessary for securing a gelatine relief suitable for his purpose is about four hours, the negative being placed eighteen inches from the light, several printing-frames being, of course, arranged around one light.

One singular point is worth noting in the matter. As light loses in intensity in the ratio of the square of its distance from its source, and the rays which reach the margin of the 10 by 8 plate are necessarily further from the point of light emitted by the carbon points than the centre of the plate, it follows that the margins receive less illumination than the centre. This, at first sight, would appear to present a difficulty. But in the case of most negatives there is fortunately a compensating quality. In the majority of instances there is a slight falling off in the illumination of the negative towards the margins, which are, therefore, slightly less dense than the centre; so that a light of less intensity passing through the margins does as much work as the intenser light passing through the central portions.

Another peculiarity of the electric light is worth noting. It possesses much greater penetrating power than sunlight, so that a negative which with sunlight would give a flat

image, with very little relief, yields with the electric light deeply recessed hollows, and great relief. In other words, a much denser negative is required for sunlight-printing than is required with electric-light printing. The relation of the lights in intensity, as measured by the exposure—the negative being 18 inches from the electric light—is as 1 to 24; that is, sunlight would effect in ten minutes what the electric light requires four hours to produce.

### VISITS TO NOTEWORTHY STUDIOS.

#### M. ADAM-SALOMON'S STUDIO—SECOND VISIT.

LET US now renew our visit to the studio of M. Salomon. It is ten o'clock on a fine October morning, and the artist comes from his sculptural *atelier* covered with the clay and plaster with which he has been hard at work, we learn, since sunrise, between six and seven o'clock, for his devotion to two professions demands the due apportionment and economizing of time. We ascend to the studio we have described, and he proceeds to pose a lady. Finding that she wears some elastic jupon or erinoline which distends her dress instead of allowing it to fall in simple folds easy of control and arrangement, he decides upon a standing position, the erinoline skirt being quite unmanageable for graceful folds in a sitting figure. The dress is of a somewhat light silk, scarcely effective for pictorial purposes, and he determines that a black lace shawl shall supplement it. The lady is first of all requested to stand perfectly easily upon, and supported by, the body-rest we described in our last, and, when an easy position has been secured, presenting little more than the profile of the figure to the camera, the face inclining from the light, the lace shawl is arranged in graceful festoon-like folds, so as to fall over the principal part of the skirt of the dress. It is attached by a pin to the wooden body-rest behind, and held in front carelessly by one of the hands, which droop easily, loosely crossed over each other. The general arrangement being secured, M. Salomon steps back a few paces and contemplates the effect, never looking in the camera. A dark mass is now required, and a velvet-covered chair is placed behind the lady, and a crimson curtain of silk brocade or tabaret is arranged in fold, partially resting on the chair, the general line of the curtain repeating, but varying, the chief lines in the figure. This same curtain, on being placed in shadow, is dark, but here it was placed in the light, so that it repeated, in a slightly lower degree, the light tone of the dress, whilst it cast a shadow on the background, throwing it back and giving relief and solidity to the figure and accessories in front of it. After a glance at the general effect, the blinds are modified a little, so as, in this instance, to concentrate the light less; and the portion of the background in front of the figure is then brought round tolerably close to the figure,

and nearly facing the strong side-light. Last of all, the head-rest was placed in position, the face turning a little more than the body towards the camera and the light. Until this moment the image in the camera has never been examined, but a glance towards the lens has been given now and then whilst arranging, to observe the relation between it and the model. The position and accessories having been satisfactorily arranged, the image on the ground glass is examined and focussed, and, without the delay of more than two or three moments, the exposure commences. It is only fifteen seconds, and after a brief rest and a slight modification in the position of the head, a second plate is exposed for about the same time, two dark slides with prepared plates having been just before handed from the dark room through a small aperture or door behind the background, through which, after exposure, they pass back again into the hands of an assistant for development.

Whilst the plate is developing, we will glance for a moment at some further arrangements of the studio, which are not shown in the sketch in our last. The camera and lens are protected from the light by a light frame-work, which projects about twenty inches in front and behind, and over which a black cloth is hung. This, in front, protects the lens from diffused light, and behind enables the operator to stand conveniently under it whilst examining the image on the ground glass.

One of the subjects of much discussion has been the light and shade upon the background, which many have supposed to be chiefly due to masking or sunning down in the printing. That such aids to effect may occasionally be used is quite possible; but, as a rule, this is clearly not necessary, as the effects are easily obtained in the studio. We have before described, as one means to the end, a canopy attached to the background tolerably close to the head of the sitter, casting a shadow on the upper portion of the plate. But a more important means of securing light and shade on the background consists in the position it often occupies in relation to the side-light. Unlike the common practice of photographers, M. Salomon does not take pains to place the background quite parallel with the camera. In many instances, whilst one end is placed in the shadow quite behind the side-light and at a good distance behind the sitter, the other end is brought round so to receive a full amount of direct light from the side window, and is also brought tolerably close to the sitter. This arrangement effects two or three objects: one end of the background becomes in the picture very dark, whilst the other is moderately light, and so aids the effect of light and shade in the picture. Further, the background being placed in this position, some idea of which will be formed from its position in our diagram in the last number, it serves in some degree to reflect a little light on the retiring and shaded half of the sitter. The direct light from the side, which illuminates one side of the sitter, also reaches the background, against which the shadowed side of the sitter is relieved; whilst the part of the background against which the lighted side of the sitter appears, being placed back, escapes this light. It will thus be seen that, in the picture, the lighted side of the face appears against the shadowed side of the background, and the shadowed side of the head against the lighted side of the background, a mode of arrangement which conduces very much to the sense of relief and solidity in the head, and gives the retiring character to the background, producing an effect of space and atmosphere. This mode of treatment may frequently be observed in the portraits by Sir Joshua Reynolds.

The negatives are now developed, and brought by M. Salomon into the studio. They are both technically excellent, clean, and brilliant, with a few points of very dense high light, much gradation, occasional touches—though in this case very few—of bare glass in the deepest shadows. They have been developed with iron and intensified with the same solution to which a few drops of nitrate solution have been added. For fixing, a strong solution of cyanide

is used, and occasionally, if desirable, a little local intensifying is produced by the application of iron and silver to certain parts of the plate after fixing. The chief point which engrosses M. Salomon's attention in examining the negatives is the modelling in the face, which, to satisfy him, must accurately repeat the light and shade he had seen on the face in lighting and arranging it; his education as a sculptor rendering him peculiarly quick to feel and exacting in securing this modelling.

Another lady follows: and here, to the artist's delight, there is no crinoline, and a sitting position is selected. A blonde English girl of eighteen is the sitter. She is placed in a chair, profile to the camera, the elbow resting on the table, the head on the hand, and a book before her, a little pains being given to break the continuity of light on its edges by giving dog's ears to the corners of the leaves. She wears a black silk dress with broad black velvet trimming edged with white lace, the spotty effect of which gave us apprehension for the result, but in M. Salomon seemed to cause but little concern, the reason for which we saw hereafter. The soft and yielding folds of the dress, undistended by any obstinately elastic and balloon-like japon underneath, were carefully manipulated into the folds which the sculptor knew so well how to arrange. The aim appeared throughout to bring the ridge of a fold prominently into the light, and to make the furrow behind it deep, and shaded by the fold from the light. All the principal folds were arranged so that the light reached them, and cast their shadows definitely in one direction. In this instance there was more material to work with, and the artist became more deeply interested in its arrangement. After placing the sitter in the chair, the general outline of the composition was arranged, the curtain being placed so as to fall in folds in some degree repeating those of the dress, and the folds of the table-cloth in front were also arranged so as to form similar lines with slight variation. The table was a small square one, and we noticed that the corner was generally placed opposite the camera, and the cover arranged in a massive fold at that corner. It will be seen by those familiar with artistic composition that the angular form here prevailed, all the lines running diagonally across the plate from top to bottom, the balancing line consisting of the white edge of the book, which was leaning against a pile of other books on the table. At the commencement of the sitting he asked the friends who were present to continue to converse with the sitter upon any topic but the coming portrait, which the sitter was requested to forget, leaving entirely all responsibility in M. Salomon's hands. He also seemed to forget the presence of any animate being, becoming absorbed in the treatment of his subject, which seemed in his hands like the modelling clay, and almost as submissive and plastic. A fold here is arranged, and a lock of hair there; the hands are gently manipulated, the position of each finger being gently but certainly modified. A quiet, low-toned commentary is kept up by the artist, half-suggestive instruction or encouragement to the sitter, and half soliloquy, "*La, la! Bien! Restez-vous tranquille,*" &c., delivered in a quiet, reassuring tone. In every instance of several sitters we saw, the trust in the artist's skill ensured by his reputation, and the magnetic influence of his manner, which expressed perfect confidence in his own operations, had a most beneficial influence on the sitter, tending at once to ease and steadiness.

Of this young lady four portraits were taken, with slightly different views of the face, each plate receiving fifteen seconds' exposure; each negative being good, and evidently very fully exposed. The lens was used with full aperture; it was, indeed, one of the old character, not supplied with any stops at all. These negatives exhibited numbers of small spaces of bare glass in the deepest shadows, the white cuffs being the only dense points in which the deposit was absolutely opaque; the densest lights in the face readily showing the interposition of any object placed at the back of the plate when it was held up to the light. The negatives were

of a rich, good colour, very full of gradation, and possessing plenty of deposit in all the lights and half lights. Although they possessed something of the positive character when examined by reflected light, they were not meagre or thin negatives, but were full-bodied and rich; alike without hardness or the unnecessary deposit which increases the time of printing without adding to the vigour of the print.

Some gentlemen followed, and the operations proceeded in a similar manner. M. Salomon, in many instances, seated himself to indicate the position to be assumed. In rarely any instance was the sitter moved after being once placed, especial care being taken to avoid worrying or disturbing the equanimity of the sitter. The accessories, the camera, and the arrangement of light are all modified to suit the position once assumed. If, when the sitter has rested his arm upon the table, it is found to be too high or too low for comfort, the height is adjusted at once by means of the Archimedean screw without disturbing the sitter.

In one or two cases, where a dark red beard had to be dealt with, it received a judicious touch from the puff and powder, to secure detail. The time of sitting of each of the gentlemen on the same morning was about twenty-five seconds. Comparatively little modification of the light appears to be necessary in ordinary work. The expanse of stippled glass in the skylight gives a soft general illumination, and prevents the existence of any black shadows without detail. The clear side-light then gives a pronounced character to the principal lights. Where great vigour and contrast are required, the blinds are drawn so as to contract the space of clear light; and where a softer and more quietly harmonious effect was desired, the lateral expanse of side-light was increased by withdrawing the blinds.

In dealing with gentlemen, as with ladies, the sculptor was apparent in the operation. Each fold in a coat was carefully considered and arranged so as to receive a definite light, and cast a shadow. The idea of the sculptor manipulating his modelling clay was again manifest. So far as the brief space of time which a photographer possesses with his client permits, M. Salomon aims at producing what strikes him—and his perception is keen and rapid—of the characteristic traits of his sitters. On the young English girl he aimed at simplicity of effect; in the matron he sought more of graceful dignity. In a journalist, whose portrait was taken whilst we were present, he aimed at more severe dignity of style. A cloak of port wine-coloured velvet was thrown over one shoulder, and the column was, for the only time during our visit, brought into requisition, and prevalence of vertical lines, with a tendency to squareness instead of curves, prevailed in the composition.

As we have before said, and as is shown in the diagram in our last, the camera is always in the corner next the side-light, whilst the sitter is nearer the middle of the room. It is to be observed, however, that although the background is placed so as to partially front the side light, the sitter never faces it, but is invariably quartered in greater or less degree from it, the soft top light preventing, as we have said, black opaque shadows on the retiring side, which is turned from the dominant light.

Although deeply interested in his work, and sparing no pains in making an effective picture and characteristic likeness, scarcely ever using the same accessories on two pictures in succession, M. Salomon is rapid in obtaining results, chiefly because no time is wasted. There is no changing of position, and every touch in arrangement tells; and whilst there is no stern adjuration to keep still, but a cheery and humorous series of remarks, continued often during the exposure, there are few cases of movement. During little more than three hours of one morning, when we were present, not less than eighteen large plates were exposed, and a negative technically good in each instance obtained.

Our visit on this occasion has extended quite long enough, and we have minutely detailed operations; not because in much that we have described there is anything strictly new,

but because we know that so many readers are anxious to know every point in the operations by which such magnificent results are produced. We must, however, defer a few farther particulars of interest until our next.

#### SERIOUS FIRE AT MR. CLAUDET'S STUDIO IN REGENT STREET.

A SAD illustration of the gregarious character of troubles has just occurred in the disastrous fire at Mr. H. Claudet's studio on the evening of Thursday, the 23rd instant, just one month after the sudden death of Mr. Claudet, senior. The fire was discovered between nine and ten at night, within three hours after the premises had been closed and left by some of the assistants; and although it was speedily got under, it was not until enormous and irreparable damage had been effected.

We visited the ruins a day or two ago, and have rarely seen a more distressing spectacle. The reception room was one of the most elegantly decorated and appointed rooms in London, and cost the elder Mr. Claudet years of thought and effort, besides a very large amount of expense. The paintings in the panels, of allegorical and emblematical subjects in keeping with the place, designed and painted under Mr. Claudet's instructions, by a clever French artist, cost upwards of four hundred pounds, and the decorative fittings of the place nearly three hundred more. These are now simply blackened and blistered canvas and ashes. A couple of magnificent table stereo stands, magnificently carved by Harry Rogers, which cost two hundred and fifty pounds apiece, are now simply a few pieces of charred wood; and scattered near, a number of Daguerreotype plates on the surfaces of which, here and there, a portion of a ghostly face is seen amid the half melted metal, the sole remains of some exceedingly choice and carefully coloured stereoscopic portraits of beautiful women. The walls and stands and glass cases were crowded with very elaborately finished specimens in water colours and oil, many of the latter enlargements; the whole of these are utterly destroyed. And, saddest of all in this part of the destruction, was every existing portrait of the late Mr. Claudet. Many of these had been taken at various periods of his life, and finished with much care by the painter. They had all been gathered together from different parts of the establishment a few days before, and put aside in the specimen room with a view to division amongst the members of his family; and every one is consumed. The whole of the reception room, in fact, and its contents, now form one scattered heap of ashes.

Passing thence through the office into the late Mr. Claudet's private room, both being on the same floor and behind the reception room, a still more melancholy loss is found. In this private room were collected the experimental results of Mr. Claudet's scientific life. From the first days of the Daguerreotype process Mr. Claudet had been an earnest, active, and successful experimentalist, and he was, also, a systematic conserver of the results of his work. In this private room were collected the examples of the various experiments in the Daguerreotype process, from the earliest portrait of himself—stretched on his back, because the plate required upwards of a quarter of an hour's exposure—down to the most recent illustrations of the value of accelerators. Here were Daguerreotype etchings; examples of the work of curious lenses; a large series of illustrations of the peculiarities of binocular vision, and the apparatus belonging thereto; illustrations of the various optical theories and mathematical contrivances which absorbed much of Mr. Claudet's attention. All these are utterly and irretrievably destroyed. Here, in a desk, also, were a number of documents, notes, and memoranda of experiments, historical data, &c., in which we fear that our readers have sustained the loss of some interesting records; for they were documents which Mr. Henry Claudet had recently been collecting for us, as the material for a memoir of Mr. Claudet and his

scientific labours, especially in relation to the early history of photography. These are unfortunately all burnt; some of the documents exist in duplicate, but others are beyond replacing.

Upwards of twenty thousand negatives are destroyed, many of them being those taken within the last two or three years. The dark-room and laboratory fortunately escaped, and the studio and apparatus, although injured, were not destroyed. The chief damage was confined to the reception room, business office, Mr. Claudet's private room, the waiting and dressing rooms, and the corridors. We are glad to learn that Mr. Claudet was assured; but much that is destroyed—such as pictures and decorations—were not assured, and much more is of a character which constitutes an utterly irreparable loss.

The cause of the fire is at the present moment a mystery. The firemen attribute it to the over-heating of hot air pipes; but the truth is, the establishment was warmed with hot water pipes, and the fire clearly did not commence at the fire by which the water is heated. Mr. H. Claudet is satisfied that the origin of the fire cannot be traced to these pipes, but is unable at present to assign to it even a probable cause. We believe that he will speedily open premises in the immediate neighbourhood to carry on his professional engagements. We are sure that he will have the sympathies of the photographic world under the accumulated trials which have overtaken him.

### Foreign Miscellanea.

At the December meeting of the French Photographie Society M. Niepce de St. Victor presented the members with a copy of a new Memoir on Heliography, which he has just published.

At the same meeting, M. Auguste Brun called attention to an improved developer, containing sulphate of copper, which is said to bring out the most perfect detail in the negative; the use of pyrogallie acid is eschewed, and the solution prepared as follows:—

Water	...	...	1,000 cub. cents.
Double sulphate of iron and ammonia	...	...	40 grammes
Pure sulphate of copper	...	...	20 "
Tartaric acid	...	...	10 "
White gelatine	...	...	3 "

M. Brun likewise states that he has derived considerable benefit by adding a small quantity of white honey to his collodion; the honey is dissolved in a small quantity of alcohol, which is afterwards used in the preparation of the collodion.

The English correspondent of the *Moniteur de la Photographie* (Dr. Phipson) makes known a humorous suggestion, made to him by an officer in the army, with reference to an application of photography to military purposes. Instead of keeping a battalion of soldiers shivering on parade for a couple of hours while the muster-roll is being called over, it is suggested that a photograph of the men should be taken, which being afterwards examined by the Sergeant-Major by means of a magnifier would show the exact state of the ranks and who were the defaulters.

The *Photographische Mittheilungen* of January presents its readers with a photographic specimen printed upon Obernetter's collodio-chloride paper. The pictures are said to be very excellent examples of what can be done with the new material. But the most interesting circumstance connected with the pictures is the fact that the majority of them were produced by development, and these come so near in point of beauty to prints obtained in the ordinary manner, that it is difficult, even for practised eyes, to find any difference between them. The only way in which they materially differ from one another is on the reverse side of the prints, the backs of those produced by development bearing traces

of a few faint spots. The developed pictures were obtained by printing a faint outline, and developing the same with—

Water	...	...	...4,000 parts
Pyrogallie acid	...	...	2 "
Citric acid	...	...	1 to 2 "

If the operation of development proceeds too slowly, a few drops of silver solution are added; the picture is brought out vigorously, and afterwards washed, toned, and fixed in the ordinary manner. For printing by development the paper must be perfectly new.

A German Chemical Society is being formed in Berlin under the presidency of Dr. Hoffmann; Dr. Vogel and M. E. Sehering have been appointed on the Provisional Committee.

M. Malmström, of Skard, in Sweden, has forwarded to the Berlin Photographie Society a description of an apparatus used by him for operating with wet plates in the open air without the aid of a tent. It consists of a bellows camera, under the focussing-board of which is attached a box containing four vertical baths. The plate is collodionized, and fixed into the box. By means of an arrangement it is made to pass into the first bath to be sensitized; it is then exposed, and afterwards treated successively in the developing, intensifying, and fixing baths.

The *Mittheilungen* contains a detailed description of the studio and workrooms attached to the establishment of MM. Rabending and Monekhoven, at Vienna.

M. A. L. Neyt, in a communication to the *Bulletin Belge* on the preservation and restoration of negatives, asserts that he has discovered the true cause of the rising of the films. He states that in the majority of cases negatives are stored away in racks against a damp wall, and so close together that it is impossible for a current of air to circulate among them. The consequence is, that during damp weather, drops of moisture become deposited upon the plates, and remain there for a considerable period, long after warm dry weather has set in. It is for this reason that the injury to the film is always observed in the centre of the plates and not at the borders, which have a better chance of becoming dry. M. Neyt recommends the usual method of restoring negatives injured in this manner, viz., by subjecting them for several hours to the action of alcoholic vapour.

In the *Photographische Correspondenz* M. C. Haack describes the apparatus used by him when manipulating with dry plates in the open air. The construction is by no means of a novel description: an oblong box has an opening at each end for the insertion of the arms of the operator, and at the top is another orifice furnished with yellow glass to look through. There is, besides, a small window of yellow glass and a door opening into the apparatus, by which the box of dry plates and the dark frame are placed inside. With this arrangement the plates are easily removed from the box to the dark slide, and vice versa.

The *Photographisches Archiv* of last month contains no especial novelty.

### PICTORIAL EFFECT IN PHOTOGRAPHY;

BEING LESSONS IN

COMPOSITION AND CHIAROSCURA FOR PHOTOGRAPHERS.

BY H. P. ROBINSON.

CHAPTER I.

"Trace me in the tedious ways of art."—*Shakespeare*.

"I have been looking over your books, and can find none but works on the most hopeless subjects:—'The Philosophy of the Beautiful,' 'Du Vrai, du Beau, et du Bien,' 'Cours d'Esthétique,' 'Kunst und Alterthum,' and other such like 'Kritische Walder.'"—*Pine Art Quarterly Review*.

THERE has been so much written on art in its relation to photography, which, when applied, has been found to be of very little use—so much talking, as Carlyle says, "from the teeth outwards," upon this matter—that it is with the greatest diffidence and reluctance I have consented to write, or compile, a series of papers on the subject. Their aim

will be to set forth the laws which govern—as far as laws can be applied to a subject which depends in some measure on taste and feeling—the arrangement of a picture, so that it shall have the greatest amount of pictorial effect, and to illustrate by examples those broad principles without regard to which imitation, however minute or however faithful, is not picturesque, and does not rise to the dignity of art.

In promising, at the outset, to be as practical as possible, I know I am sacrificing some advantages to myself, and much ease of writing, besides the *écrit* that often follows and rewards the inventor of grandly-sounding sentences, easy to write, but difficult to read, and still more difficult to understand. Those who represent art as a kind of mystery, an inspiration, a gift of the gods to special favorites, often receive the credence of the ignorant, as, in assuming the language of the oracle, they are supposed by the uninstructed to possess the inspiration, and hence, until the imposture is discovered, they receive more attention than he who endeavours to show that there is a pathway open in the direction of the temple of art which all may tread, even if all do not reach the inner sanctuary. Notwithstanding all this, my object will be to write as clearly and definitely as possible, that I may be understood by, and be of use to, all who honour me with their attention.

Many works have been written on the Art of Composition. A series of articles on the subject, of especial merit, by Mr. Lake Price, who is well known as a painter and photographer, appeared in the early volumes of the *Photographic News*, but no work has hitherto been published that sufficiently applied—or, indeed, attempted to apply—especially to photography.

In this series of papers I shall have not a word to say on the poetry of art; that is a question on which it is difficult to write so as to be really understood, except by those who have had a long education in art. I shall confine myself to what may be called the construction of a picture: in fact, I propose to deal with the body, or perhaps the skeleton, and not the soul; with the tangible, not the intangible; with that which can be taught, not that which must be felt. Neither shall I attempt to go into the mysteries of the science of composition, which only can be of use to painters who have command over every line that appears in their works. Photographers, although a wide scope for artistic effect is open to them, have not the facilities which other artists possess of making material alterations in landscapes and views embracing wide expanses, neither have they so much power of improvement in figure subjects, although much may be done by skill and judgment in that way; but they have open to them the possibility of modifying, and, being free agents, they have the power of refusing to delineate, subjects which by no efforts of theirs will ever make effective pictures. It is a too common occurrence with photographers to overlook the inadaptability of a scene to artistic treatment, merely because they think it lends itself to the facility which their art possesses of rendering minutiae and unimportant detail perfectly. To many this rendering of detail and the obtaining of sharp pictures is all that is considered necessary to constitute perfection; and the reason for this is, that they have no knowledge of, and therefore can take no interest in, the representation of nature as it would be presented to the eye by a well-trained painter.

It must be confessed, and distinctly understood, that photography has its limits. Whilst it will be necessary to explain the laws of composition in their entirety, the applicability of these laws in photography is limited by the comparatively scant plasticity of the photographer's tools—light as it can be employed by lenses and chemicals. Therefore, as I proceed with the rules of composition as far as they have been reduced to a system, or rather a *quasi* system, it will be my aim to endeavour to indicate what can be done by photography, and how; assuming throughout, however, that the student is familiar with photography and the capability of the appliances at his disposal. In doing

this, I shall bear in mind the Italian proverb, "He is a fool who does not profit by the experience of others," and shall not hesitate to avail myself of hints from every author I have met with who contains ideas worth placing before my reader, illustrating my remarks with engravings from the works of well-known painters, with occasional sketches of photographs in which the principles defined by the art of composition have aided the photographer in his choice of subject, in the arrangement of his sitter, or in his management of light and shade.

Some might ask, Of what use would a knowledge of pictorial arrangement be to photographers who have, especially in landscape and architecture, to deal with subjects over which they have but little control? To admit this would be to deny that the works of one photographer were better than another, which would be untrue. It must be admitted, by the most determined opponent of photography as a fine art, that the same object represented by different photographers will produce different results, and this invariably, not only because the one man uses different lenses and chemicals to the other, but because there is something different in each man's mind, which, somehow, gets communicated to his fingers' ends, and thence to his pictures. This admitted, it easily follows that original interpretation of nature is possible to photographers—limited, I admit, but sufficient to stamp the impress of the author on certain works, so that they can be as easily selected and named by those familiar with photographs as paintings are ascribed to their various authors by those who have an intimate knowledge of pictures. To make this quite clear, I will dilate a little further on this subject, for it is of importance, at the outset, to prove that superior results are produced by superior knowledge, not only of the use of the materials employed in photography, but by an acquaintance with art, or the whole purpose of the present treatise falls to the ground.

Given a certain object to be photographed by several different operators: no exact point of sight shall be indicated, but the stand-point shall be limited to a certain area. What will be the result? Say there are ten prints: one will be so much superior to the other that you would fancy the producer had everything—wind, light, &c.—in his favour; while the others will appear to have suffered under many disadvantages. This picture will be found to have been taken by the one in the ten (and, I fear, that proportion is too large) who has been a student of art. By his choice of the point of view, by the placing of a figure, by the selection of the time of day, or by over-exposure or under-development, or by the reverse, producing soft, delicate, atmospheric effects, or brilliant contrasts, as may be required, the photographer can so render his interpretation of the scene either a dry matter-of-fact map of the view, or a translation of the landscape so admirably suited to the subject, as seen under its best aspects, as to give evident indications of what is called feeling in art, and which almost rises into poetry; the result often differing marvellously from the horrors perpetrated by means of our beautiful art in the hands of those who only know that if a piece of glass is prepared and treated in a certain manner, it will result in the production of an image of the object which has been projected on the screen of the camera by the lens.

It is not only the cultivated and critical eye that demands good composition in works of art, but the ignorant and uneducated feel a pleasure—of which they do not know the cause—in a sense of fitness and symmetry, balance and support.

#### BLISTERING OF ALBUMINIZED PAPER.

WHY do albuminized prints sometimes blister after fixing?—a question that has been often put to editors of photographic journals, but the reasons given have been, I think unsatisfactory.

I propose to give you what I consider, from repeated experiment and observation, to be the primary and true cause.

Years back, before the carte-de-visite mania, Rive paper was the only kind found to blister; but with the carte-de-visite came the general desire to have more highly-albuminized paper, more gloss, and more brilliancy in the prints. Consequently, of late years, all papers, either Saxe or Rive, have been (during the summer months) occasionally liable to blister. I say consequently, as it is just the highly-albuminized sample which is most prone to the defect, because the albumen is most difficult to coagulate.

The remedy is, *thoroughly coagulate the albumen on the paper*, then try your best, and you cannot produce blistered prints.

Certain conditions are required to produce blisters; viz., a thick, dry, horny film of albumen, and either a weak solution of silver or a short time of floating; just as you avoid these, you avoid blisters.

I had some paper last summer the albumen on which was very difficult to coagulate with silver solution then in use; it blistered so perfectly that the film of albumen could be easily stripped off the paper. I at once procured some prepared with diluted albumen, and lost some gloss by the change, and lost sight of blisters also. The troublesome paper was laid aside until we had a week or two of damp weather, when, it being less dry and horny, the silver solution easily permeated and coagulated the albumen perfectly, and the prints done on it were free from blisters.

I have just secured Mr. Hughes' "Curious Experience" in the PHOTOGRAPHIC NEWS ALMANAC. He does not record the strength of the silver solution he used for his double-albuminized paper; but for such I should use a very strong solution. If Mr. Hughes is tempted to try again, and could sensitize the paper soon after albuminizing it, and before the albumen got too dry and horny, he would succeed better; or, if he was disposed to try spirit again, try it thus: float or sponge the back of the paper with the spirit, so as to soak it enough to coagulate that stratum of albumen lying next the paper, and, without drying it, sensitize on a strong silver solution, and he will probably succeed still better. But, in coagulating albumen with spirit of wine, it must be borne in mind that the spirit is a mixture of absolute alcohol and water, and that it is the absolute alcohol that is abstracted from the water in the process, and to so great an extent that the spirit is quickly reduced below coagulating power; hence Mr. Hughes' curious experience.

Again, when Mr. England read his paper on "A Modification of the Collodio-Albumen Process," a member considered the final silver solution too strong. Mr. England replied that he had tried a weaker solution, but the film blistered, but with the stronger solution the film was free from blister. Was it not because the latter coagulated the albumen? Subsequently, I believe, Mr. England has reduced both silver solution and albumen (both in due proportions) with a like result.

To conclude: the albumen, whether on paper or glass, *must be completely coagulated*, or blisters will result, as uncoagulated albumen is soluble in the various solutions subsequently brought into contact with it, and thereby loosening and ultimately detaching the superimposed films from the underlying paper or glass. VESICULA.

## THE PRODUCTION OF PHOTOGRAPHIC ENLARGEMENTS.

BY D. WINSTANLEY, JUNR.

[We are favoured by Mr. Winstanley with a copy of his paper recently read before the Manchester Society, with some subsequent additions and modifications.]

The subject I had in view when I promised to read a paper before this Society was the production of artificial light for the purposes of photography, by the combustion of phosphorus vapours in an atmosphere of oxygen gas. Having experienced considerable delay in the construction of the apparatus necessary for carrying out my experiments,

I am unable to bring that subject before you this evening, and have, consequently, been compelled to select another.

At the present time, when enlarged photographs are rapidly making their way into popular favour, it seems to me a few words on the method of their production will not be uninteresting to the members of the Manchester Photographic Society. The truthfulness of a painting which has such an accurate production for its basis is no small reason for preferring a coloured photograph rather than the picture which depends for its similarity to the original entirely upon the skill of the artist. It is unfortunate, however, that our confidence in the continued beauty of a finished enlargement should be rudely dashed aside by our knowledge of the very questionable variety of permanence which, in the present state of photographic science, is all that can be expected from any picture having its origin in the decomposition of the salts of silver.

Just as the camera obscura—modified, indeed, to a greater or less extent in all its parts, to suit the particular exigencies of any individual case—is really the chief instrument required in the production of a photographic negative from nature, so the magic lantern, under various modifications, is the most important piece of apparatus used in making an enlargement from a negative.

The small picture being placed in the shorter of the conjugate foci of a portrait combination, or other suitable form of objective, and illuminated from behind, its enlarged image is projected on to the plain surface placed for its reception in the other focus; and this image is then impressed upon the paper or canvas intended as the foundation of the ultimate picture, either by out-and-out printing on chloride of silver, or by the actinic formation of a feeble or even an invisible image, which is subsequently brought out and intensified by the process of development.

When any considerable amount of amplification is required, the illumination of the enlarged picture is so much inferior to that of the small one that, in order to obtain any photographic effect in a reasonable time, it becomes necessary that the small picture should be illuminated more powerfully than is possible by the diffused light of day. The earliest instrument by which this was successfully effected is that known as the solar camera, which consists essentially of a box containing the slide for the negative, the objective, and a large lens for condensing the light, together with some mechanical appliances for moving the whole arrangement, or a mirror attached thereto, so as to allow of the sun's rays always falling upon the condensing lens, in a line at a right angle with the plane of its diameter.

That form of instrument in which this object is effected by the movement of the mirror is, I believe, generally conceded to be preferable to the other, as by its use the drawing-board employed to hold the paper during the enlarging operation always occupies the same angular position in the room.

The quadrant movement usually supplied with solar cameras for altering the position of the mirror is, to say the least of it, unsound in principle and inconvenient in practice. It frequently causes, from its imperfect action, the formation of a multiple image, and is soon rendered worthless by use from the inequality of the strains on its working parts.

That arrangement in which the mirror is supported by two substantial pillars springing from a revolving disc is infinitely to be preferred, because it is not encumbered with the defect just alluded to. To be really efficient, however, the movement of a solar camera should undoubtedly be automatic. Such a movement in actual working order I have never seen. Some time ago I had an arrangement constructed specially for this purpose, substantial enough to hold its mirror in position against a strong wind, and sufficiently delicate in its mechanism to require no more impelling force than can be furnished by a common Dutch clock. Circumstances having rendered the completion of the instrument unnecessary, and it being the property of a gentleman who

prefers to keep it in its present state, I have not had the satisfaction even of seeing this at work.

Many persons might be tempted to suppose that the illumination of the negative, by allowing the sunlight to fall upon a piece of ground glass in front of it, would be a convenient way of effecting that object. Experience has, however, shown—and, indeed, a very little reflection would determine—that this is by no means the best method that could be adopted.

The transmission of a cone of rays, converging to a point in the optical centre of the objective combination, through the transparent picture to be copied, is generally admitted to be the best method of illuminating a picture, the projected image of which it is intended to photograph.

When artificial light is made use of, a condensing lens of much shorter focus becomes requisite, because the artificial rays diverge, whilst those of the sun are parallel; and this shortness of focus is much more imperatively necessary, if the lens is intended to work in the same camera which is employed with solar light.

Which is really the very best possible kind of condenser that can be employed is a very difficult point to determine. I have made experiments with many varieties myself, and give my own preference to one of three elements; viz., two plano-convex mounted with the curved sides together, and a meniscus as the immediate recipient of the artificial rays, which are allowed to fall upon its concave surface. Such an arrangement is, beyond a doubt, far ahead of a combination formed of the two convex lenses alone.

If I were asked the question—Which is the best light that can be used for enlarging purposes? I should, without hesitation, answer that of the sun; for when it does shine uninterruptedly its light is vastly more convenient to work with than either electric, lime, or magnesium. Of artificial lights, however, I consider the lime as the most generally useful, because it is much less costly to produce, and more steady to work with than either of the others mentioned.

Many persons have, without hesitation, pitched upon one or other of the three sources of artificial light mentioned, as being much more brilliant than either of the others. Any assertions, however, which have been made on this point are wholly unreliable, inasmuch as *no quantitative scientific determinations have ever been made to decide the question*; and, if they had, it is by no means improbable that the present elementary and more or less unsatisfactory state of photometrical science might yield an answer to the question which, at some future time, would be shown to be more or less incorrect.

Any quantitative determinations, however, even though based upon a method more or less faulty, are infinitely preferable to those vague statements which have confidently fixed the choice of three in succession upon each one of that number.

To compare one light with another, without specifying exactly under what circumstances each is produced, is almost too ridiculous and stupid a thing to merit criticism.

The intensity of the electric light, for instance, may be increased at will ten, fifty, one hundred, nay, a thousandfold, or even more, by a sufficient increase of battery power when the light is produced by chemical means, or by a corresponding accession in the number of revolutions made by the armature, or in the increased length of the coil or the power of the magnets in an electro-magnetic machine. So, also, by an increase of the pressure on the gases, by a larger orifice of the jet, or by a superior quality of the calcium preparation, the intensity of the lime light may be enormously increased.

To return, however, to the application of these lights to the purposes of photographic enlarging. The objections to the electric light are—the trouble of working the batteries when its origin is galvanic; the wearing and consequent breaking down of the apparatus when it is produced by mechanical means; and the movement of the carbons, caused

by inequalities in their composition—a movement which no lamp, however ingenious in its construction, can obviate.

The objections to the lime light are—that it requires almost constant personal attention (at all events, in the absence of more perfect appliances than those at present in use); that the cakes or discs are apt to fall in pieces; and the inconvenience of making gas.

The objections to the magnesium light are—that its flame is either too large for optical purposes, as in Larkin's lamp, or moves too much, as in the American lamp.

This latter objection is not necessarily fatal to the definition of the picture; but, when it is not, a very large percentage of metal is consumed without producing any photographic effect.

Some time ago, when making comparative experiments between the lime and magnesium lights for the purpose of photo-enlarging, I obtained a print by the use of the latter light in fifteen minutes, "the lamp consuming fifteen feet of ribbon, weighing three grains to the foot, and selling at that time (March 29th, 1867), at 10s. per ounce. Upon another piece of the same sheet of iodized paper, silvered for the same length of time with the same silver solution, another enlargement was produced, without moving either the negative or the board by means of the lime light, which occupied exactly the same place as the magnesium flame did in the preceding experiment. The paper was exposed until just about the same amount of trace was visible upon it. The time was then noted, when, singularly enough, it turned out to be just fifteen minutes also. Both prints, after half an hour's development, presented an exactly similar appearance. During the lime light exposure the gases (pure oxygen and carburetted hydrogen) were under a pressure equal to that exerted by a column of water seven inches in height. The temperature of the room was 65° Fahr., and the burner from which the mixed gases issued allows 6 cubic feet of oxygen and a combining quantity of carburetted hydrogen to pass in two hours and a half, under 7 inches' pressure.

Under the circumstances of the trial, which were very fair ones, my own opinion with regard to cost was decidedly in favour of the lime light. With regard to this latter light, by-the-by, allow me to mention, in passing, the fact that gas bags are, when in daily use for commercial purposes, of very little genuine utility, because of the constantly-varying pressure to which, from the very nature of their construction, their contents are subjected; and they are, moreover, a very prolific source of vexation and disappointment. Beyond a doubt, before long, they will be almost entirely superseded by cylinders—hydraulic ones for stationary use, and condensing ones for transportation.

Having now spoken on the mechanical, the optical, and illuminating appliances needed, I will say a few words, in conclusion, on the chemistry involved in the production of prints by development, and briefly remind you of the peculiar variety of negative yielding the best results.

Iodide, bromide, and chloride of silver are the sensitive salts which, under various circumstances, individually and in all proportions of admixture, are used for the reception of the actinic impression. When the alkaline salts of the metaloids contained within the substances mentioned are mixed together, according to the order in which I have enumerated their silver compounds, and dissolved in water in about the proportion of 4, 1.25, and 1 to 100 parts of water, the most sensitive film is obtained. The image, however, acquires its full vigour with reluctance, and frequently requires intensification with gallic acid and silver. When bromide and chloride are used together in the proportion respectively of four and two per cent., a prolongation of exposure results, but with the merit of an easier accession of density. The chloride alone gives the richest modelling and depth, but is the most insensitive.

Everyone, of course, will understand that, under the circumstances to which the foregoing remarks apply, a sheet of paper is used for the reception of the picture. Paper itself is a substance which varies enormously, from the

absorbent filter paper to the waterproof enamel. The sensitiveness of the preparation greatly depends upon the paper used, and the difference from the slowest to the most rapid, on this account alone is as much as 1,600 per cent. on the latter. The fine photographic papers are, with the same preparation of iodine and silvering, just about so much more sensitive than the heavy drawing papers, which latter, however, yield by far the most beautiful prints. When under-sized papers are used, the image invariably sinks within them, which objection to the finished prints may always be removed by strongly sizing before iodizing. This may be accomplished by a sufficiently strong solution of clarified gelatine, which is the better for being altered by the action of tannic acid, or the sulphates of iron and alumina, after pouring on the paper.

The peculiar bloom and brilliance, however, of some prints (as, for instance, the one I now show you) depends upon the perfection of the balance in time and materials used in the production of the picture, and which varies with every negative and temperature. The print I now hold before you is as perfectly upon the surface of the paper as the other one; but in its production the chemicals and exposure were not as nicely balanced, and it therefore lacks the bloom.

Prolonged exposure, under-development, and a small proportion of the salts of iodine in comparison with those of chlorine, all tend to make the picture red; whilst a slaty colour is obtained by the reverse of these. Red pictures, however, may always be toned after fixing by an alkaline solution of gold.

From sixty to seventy grains of nitrate of silver to the ounce of water, with a drop or two of acetic acid, is a convenient formula for the silver solution, which is best applied by brushing over the paper with a strip of swan's-down cotton, using the smallest proportion of silver required. The purity of the silver bath is one of the most essential conditions required in the production of clean work.

The development and fixing are effected by the use of saturated solutions of gallic acid and hyposulphite of soda. The amount of exposure required varies, with circumstances, from three seconds to a couple of hours.

The best kind of negative is one which has been fully exposed, developed without fogging, and left entirely unintensified. In fact, merely a slightly over-done positive. The process of enlarging by the lime light and by development is one of much more certainty than is generally imagined. I seldom have more than three or four per cent. of failures, and frequently obtain quite up to the mark without retouching.

The sundry imperfections of arrangement, style, and diction, which you will have perceived in this paper I trust you will look upon leniently when I tell you that it was written after a tedious day's work, at a late hour last evening.

I have no doubt, however, that with all its imperfections on its head, it will have excited amongst you some little amount of interest in a process which, when applied to portraiture, adds to the rational luxuries of our home; and, when used for the delineations of morbid anatomy, assists the medical student in acquiring that knowledge of disease which often enables him, in his professional career, to arrest and overcome a malady ere it becomes necessary for the preservation of vitality to afflict the suffering patient with "the terrors of the knife."

#### LECTURES ON ART.\*

In commencing the second lecture, and urging upon those who really take an interest in art the value and importance of education in its principles and position, the lecturer said he had, on the last occasion, referred to it as a means of increasing their enjoyment in looking at works of art, and of giving them self-reliance in forming a judgment on the merits

of a picture or a piece of sculpture. He should endeavour to place before them the various recommendations that a study of art possesses beyond its charm as an exponent of sentiment or of beauty, whether in form or colour. The public was not only generally uneducated in practical art, but it was equally uninformed in its history and the important functions it fulfilled as a contemporary record of the state of nations and of their civilization, when the more ancient works were produced. As illustrations of the condition and habits of the people amongst whom it was, in its first ages, practised, the remains of old time had an interest far beyond what any modern art could offer. Monuments of sculpture, especially, were, at one time, the only records of memorable events. They portrayed the great acts of kings, heroes, and conquerors. They marked important historical incidents; and from them we had acquired an insight into the mythology and the poetry of the ancients. In these representations we had most curious and reliable authority for the costume and habits of remote nations of whom there was no written or other recorded account. Here, then, they stood out with an interest entirely their own, and independent of any recommendation as regarded art excellence. There could be few present who had not seen the sculptures from Egypt, Spain, Hindustan, and from early Greece and Asia Minor, now collected in our British Museum. Some of these were of extraordinary antiquity, and we felt grateful for their preservation, while we stood, with a feeling akin to veneration, before works executed long prior to any written history. The monuments of Egypt probably mounted up to not less than 2,000 years before the Christian era. The sculptures brought from Nineveh and its neighbourhood exhibited a comparative perfection of workmanship that showed long practice; yet we knew that the wonderful city from whose ruins they were exhumed was utterly destroyed above 600 years before Christ. This comprehended a period of nearly 2,500 years, and many of the sculptures must have been executed long before this event. Incidentally, the peculiar symbolic treatment of these monuments was explained, in the union of intelligence, force, and motion or activity, in the colossal and other figures where the human head appeared joined to the powerful muscular body and legs of the lion or bull, while enormous wings expressed the capability of rapid motion. The sculptures of the Parthenon from Athens, though not amongst the earliest works of Greece that might be referred to, had also that extra interest which was afforded by the certainty that from the age of Pericles all the greatest men of ancient classical times—generals, poets, historians, philosophers—had contemplated and doubtless admired those very productions. In the larger number of the older works of Assyria and Egypt there were the most minute representations, both in painting and sculpture, of the everyday habits of the different nations; their wars and conquests, their amusements, their occupations in handicraft, their building, boating—in short, all the various business of life. Here, surely, was sufficient to give an absorbing interest to representative art, simply in its function of illustrating human life and progress.

The lecturer then proceeded to give a rapid review of the different schools of sculpture from the most ancient period; and took occasion, after still further extending his survey, to return to the proposition with which he set out—namely, that there were many grounds of interest to recommend art to the attention of thoughtful and cultivated persons beyond its attractions as a means of mere representation or imitation, and as the outward expression of sentiment and beauty. He concluded by hoping he had succeeded in impressing this fact upon many present who, probably considering painting and sculpture only in an objective point of view, had not carried their interest in it beyond the pleasure it was capable of affording them as material art. This, of course, in these days was a great purpose of painting and sculpture; but the earlier function it fulfilled gave a dignity and character to its history which deserved the recognition of all persons of reflection and education. The higher the estimation in which any object was held the greater its interest and the reason of its attractiveness to all persons of sensibility and of cultivated minds. The lecturer said his purpose in dwelling on the uses and application of art in the earlier ages, its history and progress, independently of its material charm, was to incite this extra interest. He should be very glad if anything he had said or might say on this subject should be the cause of inducing those who attended his discourses to feel the importance of education in the history and principles of art; and to acquire themselves—and, if they had the oppor-

\* Continued from p. 11.

tunity, to extend to others—the knowledge which would so surely open to them a wide field of intellectual enjoyment and delight.

He commenced the third lecture by repeating his remarks that it seemed to be agreed that, as regards art in England, the great want of the present day is education. To induce people to care to be educated they must be interested; and it was to show them there was this interest in art beyond its material attractions that he had dwelt on the important functions of ancient sculpture, and its history and progress from the fifth century before the Christian era down to its decline in the late Roman period. To bring the subject more home to modern feeling, he should now make a rapid survey of its history from the revival to the end of the last (the eighteenth) century. It is, however, scarcely correct to call this a revival. It was rather a new birth, so different and distinct was it from the older art in its material presentation. It had one advantage in common with most archaic sculpture. Its impulse was religious, but materially it had no beauty. The neglect of ancient examples in this particular—for remains of fine works must have abounded, to say nothing of the living Nature before their eyes—suggests that this proscription of the beautiful and even ordinary true forms was intentional. The avoidance of this in Pagan art is quite intelligible in the professors of the new and purer faith, but scarcely so the willing adoption of decidedly ugly and ill-proportioned forms. The controversy which raged so long between the Eastern and Western churches throws some curious light on this subject. The former insisted that sacred personages should not be represented beautiful and attractive; and even the figure of Christ was to conform to this rule, inasmuch as it is said in Isaiah, "He hath no form or comeliness," &c. The Western church advocated the opposite doctrine, and the result is seen in the art that grew out of the two systems. The ecclesiastical art of the present day, in the former cradle and school of the beautiful—the East—is as rude and gaunt as it was in the earliest time; while in the West the contrary principle, afterwards established by the authority of Pope Adrian, led to the subsequent excellence of the school of Italy. The earlier painting and sculpture employed in the Gothic period scarcely deserves the name of fine art, wanting as it is generally in almost all art qualities. It is true it was only used for decoration; but still it professed to imitate something, and this should have been Nature. The contrast, as regards the accessorial art connected with Gothic architecture, is remarkable when compared with that employed by the great Greek artists—in the Parthenon, for instance. Here the most perfect architecture of its kind was enriched with expressive sculpture of the most perfect forms in nature; and it is this combination or union that constitutes the highest form of art. The short duration of Gothic architecture, and the constant changes it underwent, may account, in some measure, for the incompleteness of the imitative arts in connection with it. It must be borne in mind that in the short space of about three hundred years it passed through many phases—from the Romanesque to the pointed or early English style, from that to the florid or decorated, and then to the perpendicular, when it may be said to have collapsed altogether. No person of sensibility, or who has any genuine feeling for the beautiful and picturesque, can deny the charm, or altogether resist the fascination, that is found in the best examples of true Gothic architecture. But there is, unquestionably also, a positive claim to admiration in the originality, the bold fancy, the variety and play of parts, the contrivance of scenic effects in the perspective views, and in the striking contrasts in *chiaroscuro*, which are so remarkable in the monuments of this peculiar style of art. Still, with all these admissions, the lecturer said he was bound to protest against the outrages committed against truth and fitness, and, indeed, common sense, which were so constantly seen in the Gothic use of accessorial imitative art. How the fitness of nature was abused is seen when human faces of saints, kings, nuns, and ecclesiastics are found employed as corbels and brackets to bear weights, or as terminations to dripstones, or as gurgyles or draining-pipes; or when entire or truncated figures, angels or others, are seen suddenly starting from walls; their drapery clinging to them in stiff, horizontal folds instead of falling by any law of gravitation; or standing figures thrust into arched, hollow mouldings; or others dislocated and distorted to accommodate them to fill up spandrels of arches or other spaces. Still there was a promise of excellence in this Christian art, and there were signs of improvement of the most encouraging kind. Unhappily, a revolution, fatal, as it turned out, to the

progress of art, changed the character of the age. This was occasioned by the passion created for classical studies by the discovery of manuscripts and remains of Greek and Latin literature in the fifteenth and sixteenth centuries. The educated and influential classes devoted themselves to this new attraction, insisting that everything should be done to establish a pseudo-classical taste, and by the end of the eighteenth century all true art-sentiment seemed extinct. This was the state of art when Flaxman and Canova stepped in to stem the torrent of false and bad taste.

Mr. Westmacott concluded with some remarks on the late rise of art in England compared with other countries—Italy, France and Germany. In the course of these, and in commenting on the inferiority of English art, he exposed the absurdity and unfairness of the charge that the Reformation was the cause of a retrograde movement in art among us. England had no art to retrograde or to be injured at that date. All, or almost all, we had was by foreigners, who were certainly free from the supposed influence of the Reformation. They brought here the bad style of art universally prevalent on the Continent—that is, their own. In the churches of Italy, and in St. Peter's especially, the very worst taste prevailed, as may be seen in the meretricious, and sometimes even offensive, art that was allowed to appear there in ecclesiastical buildings. Certainly we had nothing of our own of this kind, whatever shortcoming in other respects might be laid to our account. The lecture closed with some general observations on the general tone of art-feeling in England at the present time.

## Correspondence.

### HYPOSULPHITE OF AMMONIA.

SIR,—In reference to the communication from Mr. Spiller in the last number (No. 499) of the *Photographic News*, on "Hyposulphite of Ammonia for Fixing," allow me to observe that the whole account of the experiment cited from "Colin Mackenzie's Treatise—One Thousand Chemical Experiments, &c.," on the action of hyposulphite of ammonia on nitrate of silver, is copied *verbatim* from my second paper on the hypsulphites in Brewster and Jameson's *Edinburgh Philosophical Journal* (1819), p. 396.

Mr. Spiller appears to consider the insoluble powder formed by adding chloride of silver to the solution first described, as pure hypsulphite of silver. It is, however, more probably a compound of that salt with hypsulphite of ammonia, atom to atom; the soluble double-salt containing two atoms of the silver-salt. Such, at least, is the view taken in the next paragraph (not copied, apparently, by Mr. Mackenzie). It runs as follows:—"29.3 grains of the soluble variety above described gave 11.9 sulphuret of silver, which agrees, within moderate limits, with a composition of two atoms of hypsulphite of ammonia + one atom hypsulphite of silver. Hence it is very probable that the insoluble variety consists of the same component salts, united atom to atom."

To procure the pure hypsulphite of silver, nitrate of silver, somewhat diluted, must be poured into a pretty strong solution of hypsulphite of soda. A copious precipitate falls—white at first, but, as the precipitation proceeds, becoming gradually dirty, and at length quite brown, especially if too much of the nitrate be added. This precipitate, separated by the filter and washed, must be treated with ammonia, which dissolves the metallic salt, but leaves the sulphuret behind which contaminated it. The ammonia being exactly neutralized by weak nitric acid, the salt precipitates in a snow-white powder, which must be separated and dried as quickly as possible by violent expression between folds of blotting-paper." The sweetness of the soluble ammoniacal salt is something astonishing. Fifteen grains of white sugar communicate a barely perceptible sweetness to 4,000 grains of water. The sweetening power of the silver compound, therefore, exceeds that of sugar in the proportion of 120 to 1.—I am sir, your obedient servant,

J. F. W. HERSHEL.

Collingwood, January 25th, 1868.

## MR. McLACHLAN'S DISCOVERY.

SIR,—Since reading Mr. Lachlan McLachlan's letter in your last number, I have felt, as it were, as if the ground were cut from under my feet; and, with your permission, I shall beg, on public grounds, that that gentleman will reconsider his determination, as others may be suffering in a like manner. Although I have been working assiduously for years at photography, it seems that all that is known as yet is mere moonshine to what Mr. McLachlan can show us. The question immediately arises, why proceed a step till he has mercy on us? We (photographers) and the public may at once cease in our present hit-or-miss style, and await the revelations of our benefactor. Second sight is generally considered to be the privilege of that land where Macs abound. But, sir, will this gentleman be so hard on the world as to delay till July or August the full taste of those joys of which, as yet, he merely hints his possession? "There's many a slip 'twixt the cup and the lip." He might (Heaven forbid!) die. Have not thousands mourned the precipitancy of that Roman emperor who slew the artificer that brought him the malleable glass vase, and said he had not confided his secret to others? Are there not advertisements in every paper that "accidents will happen?" What office could insure his life, plus our hopes? Has not some one said,—

"Where'er I go, where'er I roam,  
A voice still whispers in my ear,  
This earth is not thy home?"

In fact, the arguments are endless that might be brought to bear upon my view. In olden times, when any Mac had celebrated himself, his countrymen, as they passed his resting-place, threw a stone on the heap, and at length the mass testified by its size the respect that posterity bore him. The cairn, as it was called, should be enormous in Mr. McLachlan's case, if he performs half he promises; and I am mentally putting aside a guinea or two for the inevitable testimonial. Mr. McLachlan differs "very materially with the first chemists and photographers of the day." So I am putting in a heap—Fresenius, Hardwich, Bolley and Paul, Lake Price, Fownes, Towler, Galloway, Hassell, Faraday, and others, for a bonfire, for they never promised half as much. He also says, "Should I be mistaken, I would like to have my error pointed out to me."

Sir, to keep his mind easy. I may, I think, with some confidence, assure him, on the part of photographers, that it will be. And for his noble offer, I would remind him of that line of Virgil's that might with justice be claimed by photographers as their motto,—

"Sic vos non vobis mellificatis apes."

Sir, I cannot go on, the noise of the flourish of trumpets about me is so great.—Your obedient servant,  
January 23rd, 1868. A MAD DOCTOR.

## "CHEAP JACKS" IN PHOTOGRAPHY.

SIR,—Your correspondent "Litho," who evidently does not live in a glass house, or he would not throw stones, appears to hold the Cheap Jacks in very orthodox horror.

Sir, I am a "Cheap Jack," and I practise "the five shilling cut." I am one of "that low lot," but I believe that most of my fraternity will join me in raising an emphatic objection to the inferences of your correspondent, who says: "They (the C. J.s) have done all in their power to disgrace photography." Sir, I deny this—every word of it. I am the last to agree with excessively low prices in anything. Cheapness generally means low quality; but, often, competition forces those who have small capital either to low prices or abandonment of their trade, which they may love to practise just as well as "Litho."

Portraits at a low price were introduced to supply the people. John Smith and Sarah Stoakes may not be good models—may be ugly and ungainly to the last degree—but there is no reason why they should not have their portraits

taken. If John has a regard for Sarah, he prizes her picture, and they have the same pleasure in gratifying their relatives, &c., as the highest class. The necessity for moderately low-priced photographs is evident, make them as good as you can; but "Litho" alludes to the "Cheap Jacks" as if they were the only photographers that have any sins to answer for. I think you yourself will bear me out that hitherto high prices have not uniformly meant artistic pictures, or even good manipulation.

Sir, I object to your narrow-minded correspondent. An art or profession should be open to all. Because I charge 5s., and "Litho" gets four times as much, does it follow that he is more "worthy" than me to participate in any discovery or improvement that may be made? Can I not have the same desire to obtain the best result that lies in my power and knowledge, and the same appreciation of the artistic as he has? In fact, am I not a man and a brother? If I am ignorant, teach me; but do not exterminate me.

Sir, I do not know Mr. McLachlan, only through your Journal, but I appreciate his offer as much as any photographer can do. Although he may be, as "Litho" asserts, my enemy and the enemy of all my compatriots, I beg to propose when Mr. McLachlan has proceeded to successful demonstration of his discovery, that he be presented with some suitable testimonial of his cleverness and generosity; say a piece of plate, or gold medal and clasp, subscribed for by all classes of photographers, not excepting "Litho;" and one of the first shall be—Yours,  
H. S.

PS.—I beg to enclose my "card," which is a fair sample of general work; and I ask you, impartially, if it is not quite as well worth the price as most of the higher class people's work is worth their price? I can point to half a dozen photographers in this town, all at this price, whose work is better than mine. I find "the better the work the more custom you get," but you cannot get another shilling per dozen, however well they may be done.

[The print enclosed by our correspondent is decidedly above the average of excellence in card pictures; and we think our correspondent himself would admit that the price of five shillings per dozen does not adequately represent the value of the professional skill and other costs of production. The claims of John Smith and Sarah Stoakes to portraits of those whom they love, at prices within their means, are such as we shall not deny; but the extent and limit of those claims, and the mode in which they shall be supplied, open a wide question. We should not ignore their claims, but we should recommend that they should be supplied in a degree commensurate with the prices they can afford, exactly as all their other natural wants and desires are supplied. To do this it is not necessary that the general price of good work should be lowered for the whole public below a fairly remunerative rate in order to meet the wants of a class of small means. For instance, the card forwarded by our correspondent is not one of a person belonging to the class indicated, but one of a lady whose dress and appointments indicate the capacity of paying a fair price for a work of art. If the price were twice or thrice or four times that charged, John and Sarah might gratify their natural desire for good portraits of each other by limiting those desires to their means, and being content with (say) a quarter or a third of a dozen for five shillings. The question cannot be argued in a small space, but our correspondent must well know that in the town in which he practises his profession, the trade or profession has been ruined by a cutting competition in price, not for the benefit of the poor, but for the benefit of a class who have large means to expend in the gratification of their desires. He must know also that the tendency of the maxim of quick returns and small profits in matters of art tends to haste and slovenliness, that it demands the necessity of large productions in place of much care, of quantity instead of excellence. Our correspondent clearly does not legitimately come within the category of "Cheap Jacks" with no feeling for their art beyond the returns it brings; and he must agree with us

in deprecating the race for cheapness which has tended to reduce, in many instances, a remunerative, if not a lucrative profession into one yielding a bare living. This is a state of things which does not conduce to efforts after high excellence.—Eu.]

### CARBONATE OF AMMONIA IN THE FIXING BATH.

SIR,—As you invite remarks on the use of carbonate of ammonia in fixing solution of hypo. of soda, perhaps a short statement of my own experience may not be out of place. I have used it constantly since Mr. Spiller's formula appeared in the PHOTOGRAPHIC NEWS YEAR-BOOK, 1867. My formula is a little modified. The proportion of hypo to water is 16 per cent., and I add 4 per cent. carb. ammonia; filtering when dissolution is complete. It strikes me that the yellow spots complained of by your correspondent arose from omitting to filter. Last summer, in the studio of a friend, I recommended the use of ammonia so strongly that he agreed to try it. Hypo., carb. ammonia, and water, in the proportions I have named, were thrown into a porcelain fixing dish, and, when all was dissolved, the prints, after washing, were plunged into the fixing solution. In a few minutes they exhibited a profusion of small, white specks, about the size of the head of a pin. On examining the solution we found a number of minute grains of carb. of ammonia at the bottom; for unless very finely powdered before using, this salt dissolves much more slowly in water than hypo. Filtering would have removed the cause of those spots.

My experience goes to show that unless prints are of a deep tone to begin with, and have been their full time in the acetate of soda and gold bath, they are a good deal punished in fixing. In many instances, however, I have found that the sepia tone sometimes induced in fixing is entirely changed to a good purple-black, when the prints are washed, and finally dried.

Before using ammonia, I had often to experience the peculiar sulphur odour of the hypo solution when the prints were immersed in it. Since adopting ammonia it has never occurred to me. I never use the same solution twice. It may be fancy, but I think I see a more delicate bloom in the prints fixed by Mr. Spiller's method. It is too early yet to speak of the effects of it as a preservative of the print. I enclose one or two samples of prints fixed as I have described.—And I have the honour to be, sir, your obedient servant,

J. STOTHERT.

*Bruges, Rue Flamande 9, January 25th, 1868.*

[The prints enclosed by our correspondent are extremely clean, bright, and pure in colour.—Eu.]

### PERSISTENCY OF PHOTOGRAPHIC IMAGES ON GLASS.

SIR,—I have just experienced a singular proof of the tenacity with which a photographic image—or, rather, its ghost—may, as it were, haunt a glass plate, even under circumstances, to all seeming, quite incompatible with a visitation from such an apparition.

Six weeks ago I took two whole-plate copies from an engraving, intensifying one negative with the ferrideyanide of uranium and gold intensifier, and the other with bichloride and gold, as recommended by Mr. Winter. Intending only to keep one of these negatives, I coated both with dilute gum in lieu of varnishing, and, after printing an impression from each, condemned that treated with bichloride of mercury as in all respects inferior to its double.

After removing the film from the discarded negative with hot water, I cleaned the plate as usual with tripoli in methylated spirit, and consigned it to the box. Last week I took a copy of another picture on that identical piece of glass. It was, to all appearance, as chemically clean and fit

for use as could possibly be desired. In consequence of being compelled to use a small stop, and the rapid deterioration of light arising from the lateness of the hour, I found great difficulty in development. When at last a picture slowly began to appear, you may fancy my surprise, sir, at observing that it included the most salient features of the old subject, as well as of the new. Thus the figures of some boys sliding in the background, and a basket of fruit in the foreground of the first, as well as the heads of a mother and infant, which formed the most striking feature of the second image, were most curiously and grotesquely intermingled, the handle of the aforesaid basket resting exactly on the centre of the child's forehead. I ought to mention that the first picture occupied the plate longitudinally, and the last breadthways. I should be glad to learn whether you, sir, or any of your readers, have experienced a similar effect under corresponding circumstances.—Your obedient servant,

H. J. C. ANDREWS.

*Central Hill, Lower Norwood, January 28th, 1868.*

[We have occasionally met with similar results.—Ed.]

### Talk in the Studio.

THE LATE M. CLAUDET.—We are requested by Mr. Henry Claudet to state that a rumour to the effect that his late father was about to retire from the Photographic Society is incorrect, and manifestly based on some misconception. Up to the last he manifested a lively interest in the Society, and never to any of his friends or to his son, who was constantly in his company, intimated the slightest intention to withdraw from the Society, but, on the contrary, made repeated allusions to matters based on his intended continued connection with it. As the report that his father was about to retire from the Society on account of any personal dissatisfaction implies that a feeling of pique dictated his action, Mr. Henry Claudet asks us to deny a report which does injustice to his father's memory. A "Member of the Council," writing on the same subject, states that he spent an hour or two in the Conduit Street Exhibition, when he expressed the greatest satisfaction that the Society had secured such a successful exhibition. It is not necessary to insert our correspondent's letter, as Mr. H. Claudet's statement will correct the misconception.

PHOTOGRAPHS OF HISTORICAL DOCUMENTS.—The Corporate authorities of Exeter have resolved to reproduce a valuable collection of old and interesting memoranda, deeds, charters, and other documents now in their possession, and which have lately been brought into the light. It is proposed to photograph, photo-lithograph, and otherwise copy these very interesting records for the benefit of archaeologists, &c., &c.

AN AMERICAN ESTIMATE OF M. SALOMON'S PORTRAITS.—A letter from Mr. Pollock, an American photographer, states that examples of M. Salomon's portraits have caused as much excitement in photographic circles in the United States as in this country. Writing in our Philadelphia contemporary, he also says:—"We recently had the pleasure of a 'sitting' with M. Adam-Salomon, deservedly acknowledged by unprejudiced judges as the best portrait photographer in the world; and after carefully inspecting the arrangement of his studio, witnessing the manipulation, examining negatives and prints, all under circumstances most favourable for forming correct judgment, we are happy to add our testimony as to the simplicity of the means employed in producing wonderful results. So wonderful, indeed, are these portraits, that a large amount of jealousy, incredulity, unbelief, and prejudice exists regarding the manner of their production, giving currency to stories which have gained a wide circulation, to the effect that both negatives and prints are retouched from one end to the other—built up, in fact, with little foundation; and it is stated, as an instance of the degree to which this retouching is carried, that a picture-dealer, to whom a print had been sent to frame, accidentally allowed a drop of water to fall upon it, in endeavouring to remove which he washed the picture almost entirely out. Excellent photographers hold the same opinions, and suppose the prints carefully worked up, so great is the degree of their excellence and superiority to anything hitherto attained. In truth, however,

such is the perfection of the work, it has been remarked that one might as well gild refined gold, or paint the pure lily, in expectation of improving them, as attempt to add aught to the beauty or finish of these pictures by retouching." It should be remembered that Mr. Pollock here speaks of his own portraits, the negative of which, as well as the prints, he has in his possession.

**ANTIDOTE FOR EXTERNAL POISONING BY CYANIDE OF POTASSIUM.**—This substance is extensively used in electroplating and other arts, where its external poisoning effects produce many painful and troublesome ulcers on the hands of the workmen. The foreman of the gilding department of the American Watch Works writes to the *Boston Journal of Chemistry* that experience has taught him the most effectual remedy that can be employed in such cases, which is the protosulphate of iron in fine powder, rubbed up with raw linseed oil.—*Scientific American*.

**PHOTOGRAPHY AND PARKESINE.**—Parkesine, originally described in the pages of the *News*, is now being introduced in commerce as a substitute for ivory; and, as photographing on ivory can be readily done, and elegant results obtained, it may possibly be found advantageous to try its effects on the new material, which will be extensively used for many articles of domestic and ornamental use in lieu of the scarce and costly tusk of the elephant.

## To Correspondents.

**W. J. A. G.**—Black is very dismal and uncomfortable-looking for any portion of the interior of a studio. A dark warm grey, a chocolate brown, a port wine colour, a dark crimson or maroon, or an olive green, will all be sufficiently non-actinic in their reflections, and much more pleasant to look at. 2. There is no patent for Mrs. Cameron's process. The black colour is easily obtained by deep printing and toning. The reason they look unlike photographs is two-fold: first, they do not possess, but absolutely ignore, the sharpness and detail which is the especial characteristic of photography, and in which it excels other modes of delineation; and, second, because there is really a large amount of artistic feeling displayed in the selection and management of each subject. As a rule, a free and artistic style of treatment, a lack of definition, and prevalence of deep shadow, characterize all her pictures. 3. A rising front does not give you the same advantages as a swing back. By means of a rising front you can regulate the amount of foreground, sky, &c., to be included in your picture; by a swing-back you can do this to some extent also; but its especial purpose is, when it is necessary, to tilt the camera to secure the roof in an interior, or a spire or tower in an exterior view of a building, to enable you to keep the sensitive plate parallel with the subject depicted, and so prevent the effect of converging perpendicular lines. 4. For general work, No. 3; for architecture, No. 1 is best. 5. The quality of the tone of a print depends very much upon the quality of the negative; but it is chiefly from the amount of reduction which the negative permits in the shadows without over-printing the lights. It is quite possible to get brown tones with the acetate bath, and a very short immersion is sufficient to secure it. Our choice of a toning bath much depends on the kind of results we desire, some tones suiting one subject, some another. For a rich, warm, purple brown nothing is better than the acetate bath; for black tones, the lime bath. We very frequently improvise a bath if we require to use it at once, and have none ready, by adding a little chalk to a concentrated solution of chloride of gold, diluting with hot water, and using when cool. 6. No. 1 undoubtedly.

**A STRANGER.**—There is no association or benefit society composed of operators in London or elsewhere, that we know of.

**ARGENT.**—In producing a transparency by the process we described, the negative is placed in the outer groove of the copying-box, as indicated at C, on p. 73 of our *YEAR-BOOK*, the lens being in the centre and the ground glass at the opposite end. If convenient, it is better to work in the open air, or with the end of the copying-box containing the negative placed out of a window, simply because more light is secured.

**H. BERTON.**—The colour test of alkaloids is an exceedingly fallacious means of detecting poisons, and, if relied upon, will frequently lead to error. For instance, iodic acid and starch form the colour test for morphia; and Orfila mentions a case in which the viscera of a healthy calf gave, with the test, exactly the same reaction in colour as the viscera of one which had been poisoned with morphia. This led to the discovery that lithic acid or the lithate of ammonia (constituents of healthy urine) gave the same colour with morphia as the recognized test, iodic acid. Another eminent French authority, writing on the subject, remarks that nothing is so deceitful as a reliance on colour tests.

**R. B.**—A thick solution of india-rubber in benzole, from 20 to 30 grains to the ounce, is the best thing for mounting photographs in an album, as then all risk of cockling is avoided. 2. You can procure iodized negative collodion of any photographic dealer. 3. Float on the salting solution about three minutes, and on the silver solution three minutes. The question whether acetic acid is to be added to the gallic acid depends for its answer on whether it is present, and in what proportion, in the silver bath. Painting a negative at the back to prevent "blurring" is done, of course, after the plate is prepared. A piece of red blotting-paper, moistened and pressed to the back of the plate, answers well.

**B. B.**—The address of Messrs. Foster, Auctioneers of Works of Art, is 54, Pall Mall. The address of Messrs. Christie and Co. is King Street, St. James' Square. We are glad to hear of your continued success with the modified collodio-albumen process. Thanks for your kind remarks about the *YEAR-BOOK*.

**A PROVINCIAL PHOTOGRAPHER.**—Judging from the print you forward, the negative is forged, probably by diffused light having reached the plate. The lights may be dense, but we should say that there is considerable deposit on the shadows; hence the want of depth in the shadows. We can only tell certainly on seeing the negative.

**MRS. H. WEST.**—The bleached or white bees'-wax is used for waxing photographs; paraffine is equally good, or better for the purpose. 2. The effect of adding cyanide of potassium to a solution of nitrate of silver is to cause a precipitate of cyanide of silver, which, when filtered out, will not cause further injury. Neutralize the nitric acid in your printing bath with ammonia, and try again. 3. The price of Mr. Edge's card pictures is 1s. 6d. each. A letter addressed Preston will find him.

**YOUNG.**—The light entering above A.B. in your diagram, at an angle of 45 degrees, would not reach the sitter; but you forget that all the light does not enter at an angle of 45 degrees, but a great many angles besides, and therefore some of it will reach the sitter. A very simple plan will enable you to ascertain how much light reaches the head of the sitter. Place yourself in that position, and cast your eyes around: from every point at which you can see the sky direct light will reach the sitter. All glass through which you cannot see the sky may with advantage be covered or obscured. 2. All light which does not reach the sitter is mischievous. 3. In a lofty room it is often advisable to have curtains which can be arranged near the head of the sitter for occasional use. Blue calico is a good material. 4. Portrait lenses rarely cover so evenly or illuminate so perfectly to the edges as view lenses; and in order to get all parts defined, very small stops must be used: nothing is gained in using them for ordinary landscape work, whilst something is lost. 5. About equal.

**ALEX. AYTON.**—Thanks for the excellent examples of card portraiture. We shall have pleasure in learning the result of your contemplated modification. We are glad to learn that your visit to M. Salomon was so pleasant and so satisfactory.

**ENGINEER.**—It seems probable that what you call fog in the transparencies produced by the method in question is really increased action of light, as it often happens that a thick film is more sensitive than a thin one. In some cases a little dilution of the collodion may be desirable. A good iodizer for the purpose will consist of two grains each of iodide of ammonium and iodide of cadmium, and one grain of bromide of cadmium.

**X. L.**—We do not know in whose possession the original painting of "Belshazzar's Feast," by Martin, now is. There is an engraving of it published, but we do not know of any photographic copies to the engraving.

**A YOUNG BEGINNER.**—So long as you take care to have your yellow light in your dark room thoroughly non-actinic, there is no danger in having a sufficient amount of it to make working easy and pleasant. It is a bad thing to have too little, as you cannot then properly see what you are doing. In such a room as you describe, a window three feet by three feet will probably answer. We are glad to learn that you are well pleased with the paper.

**CHEMIST.**—It appears to us that the lenses you have in your possession ought to answer well for the purposes you mention. What difficulty have you in using them? No. 3 is a capital lens, but not sufficiently long in focus for standing card pictures.

**J. A. REED.**—When the ternu parti is used, the formulae may be made up in grains, scruples, drachms, or ounces. Thus, if you make up the formula you mention in scruples, you will have 1 scruple of pyro and 1 scruple of citric acid in about 13 ounces of water, or something like  $1\frac{1}{2}$  grains of each to an ounce. A 3 per cent. silver solution is a solution containing 3 grains of silver in 100 minims of water, or a fraction under 15 grains to the ounce of water. 2. It is the collodion containing nitrate of silver which has turned red. It may not necessarily be spoiled: try it. In any case, the collodion containing chloride is good still.

We are again compelled to leave over much interesting matter, owing to the pressure on our space; and many Correspondents also stand over until our next.

## THE ELIMINATION OF SILVER FROM THE WHITES OF ALBUMINIZED PRINTS.

ALTHOUGH it may be impossible to secure the absolute stability of pictures formed of a metal like silver in an extremely minute state of subdivision, covered with an attenuated layer of gold, every suggestion which tends to increase the permanence of such prints must be regarded as a boon to photographers generally.

Besides the sources of instability arising from carelessness in the process of fixing and washing, albuminized prints are, even when produced with the utmost care and skill, subject to two dangers: in the first place, the minute particles of silver forming the image are acted upon by sulphur and its compounds, which are always more or less present in the atmosphere. This is, however, a comparatively light matter, inasmuch as the colour of sulphide of silver, being dark, may modify the colour of the dark parts of the picture, but can scarcely obliterate or seriously aid in spoiling the picture. But the chief defect observable in a fading print is the loss of purity in the whites, which assume a yellow degraded tint, which robs the print of all beauty. If the print were perfectly fixed, no trace of silver should be left in the white paper, and it should not, consequently, be subject to any change. The insoluble silver compound formed in the albumen, which hyposulphite of soda fails to remove, is the cause of this most serious defect in the print, and hence the vital importance of all experiments tending to its removal.

The recent experiments of Mr. Spiller have shown that the hyposulphite of ammonia is much more perfect in its solvent action on this silver compound than the soda salt hitherto used. Unfortunately, there are difficulties in the way of introducing the ammonia salt into the market, of which the chief is the fact that it is so highly deliquescent that it would be difficult to keep in stock, to weigh out, and to deal with generally. How far these defects might be removed by modes of manufacture, should a general demand arise for the salt, remains to be determined. Before a demand can be created, the claims of the salt as a fixing agent must receive more extended examination, and its advantages be proved by further experience.

Mr. Cherrill's article on another page describes an interesting experiment, and offers a most important suggestion, by the adoption of which the advantages of hyposulphite of ammonia may be tested, with very little trouble and expense, by photographers generally. Mr. Cherrill has, by adding sulphate of ammonia to the bath of hyposulphite of soda, converted, by a process of double decomposition, a portion of the latter salt into hyposulphite of ammonia. The test applied to the prints so treated furnished striking evidence of the superior fixing powers of the ammonia salt. Tested with sulphide of ammonium, the whites of the prints give the slightest possible evidence of the presence of silver, a

very faint discolouration being perceptible, whilst the whites of an ordinarily fixed print, treated with the same sulphide solution, show a very definitely marked brown stain. Another print, in which a portion of the paper has been carefully preserved from any action of light by a perfectly opaque mask, shows in the whites no trace of silver whatever, after immersion for a quarter of an hour in a solution of sulphide of ammonium, which had altogether changed the colour of all portions of the print containing silver.

Mr. Cherrill endeavours in his experiment to combine two distinct advantages. Besides securing more perfect fixation and the removal of silver from the whites, he aims to obtain the oft-coveted simplicity, certainty, and rich colour obtained in the old toning-bath of hypo and gold, with the immunity from mealiness, great reduction, &c., which attended it. Theoretically we see no reason why such a toning and fixing bath, when properly prepared, should fail to yield prints of permanency equal to those produced by the method at present in use. For those who are disposed to repeat Mr. Cherrill's experiments we have one or two suggestions to make.

In the formula employed by Mr. Cherrill, two drachms of sulphate of ammonia are added to the solution containing three ounces of hyposulphite of soda, by which nearly one-fourth of the latter salt will be converted into hyposulphite of ammonia. We would counsel going a little further, and, instead of two drachms of sulphate of ammonia, use an ounce of this salt, which will convert nearly the whole of the three ounces of the soda salt into the hyposulphite of ammonia, and the full benefit of its solvent powers may thus be secured. The sulphate of soda which is also formed by the double decomposition will, of course, remain in the solution inert, and need not be regarded.

In adding gold to the fixing bath, it should be remembered that as all crystallized samples of the chloride contain a little free acid, a slight decomposition will ensue, in which sulphur will be liberated. To avoid this, we recommend that before adding the chloride of gold to the hypo, it should be dissolved in water, and five grains of carbonate of soda added to each grain of chloride of gold. Any slight excess of the soda salt, when introduced into the fixing bath, will cause the formation of a little carbonate of soda, the presence of which will be beneficial rather than injurious. A toning and fixing bath so formed will consist of a strong solution of hyposulphite of ammonia, hyposulphite of gold, a little hyposulphite of soda, and a little carbonate of ammonia. There is no reason why, in such a bath, perfect toning and fixation might not proceed at the same time. But there is this important caution to be observed: such a bath may continue its toning property long after its fixing powers are exhausted. If, therefore, it be used for some time, the print should be immersed in a second fresh bath of hyposulphite of ammonia, and soda, made as

described, but without the addition of gold. Further, it should be remembered that the immersion of the unwashed print most undoubtedly produces some degree of sulphur toning, for many years the *bete noir* of photographers. We know that some sulphur-toned prints have remained for many years without signs of change; but, until the conditions of permanent sulphur toning are fixed, we commend our readers to take the ordinary simple precautions whereby it may be avoided. This may be done, as we have shown, without giving up the combined toning and fixing bath. The subject is one worthy of the attention of experimentalists.

### THE PRACTICE OF SILVER PRINTING.

THERE are few photographic processes which have been brought to greater perfection in practice, so far as regards the production of immediate results—we put the question of final stability aside for the present—than silver printing on albuminized paper. Yet, from the correspondence which reaches us from time to time, we are satisfied that, notwithstanding all that has been written on the subject, much misconception—or, perhaps, rather, total lack of any idea—prevails as to the *rationale* of the process, and consequently at times much uncertainty in producing results. The production of good plain paper prints is still less understood, and consequently, notwithstanding the beauty of plain paper for large portraits, it has fallen of late entirely into disuse. In short, there are many points on the subject of silver printing, toning, and fixing upon which valuable systematic instruction may with advantage be imparted.

"It is always pleasant," Montaigne remarks, "to read things that are written by those who have experienced how they ought to be carried on." Cordially endorsing this dictum, we have arranged with one of our esteemed contributors who has devoted many years almost exclusively to silver printing, and who at different times has written much on the subject in desultory articles at different times, now to give a concise and systematic series of articles on the subject. Mr. Bovey, known to our readers as "The Photographers' Assistant," will accordingly commence a brief series of articles in which he will restate the whole process of silver printing, with its *rationale*, in which he will place before our readers a method which he finds unailing in simplicity, certainty, economy, and excellence of results. On the latter point we can speak in high terms, and with much confidence. Those of our readers especially interested in the series will do wisely to ask questions, or state difficulties, as the course proceeds, so that all points requiring elucidating may receive the fullest attention. The series will commence in our next.

### VISITS TO NOTEWORTHY STUDIOS.

#### M. ADAM-SALOMON'S STUDIO—THIRD VISIT.

IN making a third visit to M. Salomon's studio, we shall bring before our readers a few details gleaned in conversation with him. We find him very accessible, and courteously communicative without reserve or any pretence of mystery. He is a gentleman apparently about fifty years of age; frank, earnest, and impulsive in manner; keenly sensitive and impressive; apt and free in conversation, with a great fund of humour and ready repartee. He appears to make no secret whatever of any part of his operations, nor does he seem to think it necessary to do so. Conscious, apparently, of capacity and culture as an artist, he treats each portrait as a work of art, and aims, as a matter of course, to secure in each the best pictorial effect compatible with the faithful rendering of character. He is manifestly an enthusiastic admirer of photography, appreciating with keen delight any peculiar beauty it renders perfectly; and whilst putting forth no especial claims for his portraits, neither declaring them touched nor untouched, it manifestly amuses him that anyone should accredit to retouching the peculiar

beauties of his pictures, or assume that the pencil of the artist could surpass the pencil of nature; and he does not hesitate to challenge the closest scrutiny and comparison of negatives and prints in various stages.

"But what is M. Salomon's practice as to touching?" we have been asked by one who has read our oft-repeated statements that some of his prints are untouched, some slightly touched, and some considerably touched. We can simply answer, as we have done before, that each picture is treated in accordance with its requirements, and the more perfect the photograph, the less retouching it requires or receives. But few photographs, especially of large size, are pictorially fit for issue without undergoing a process which the late Mr. Claudet used happily to phrase as "correction." This involved no working up in the ordinary sense of the term; it involved, however, not only the stopping out of pinholes, &c., but the strengthening of the iris of a blue eye which was almost burnt out by the light; the taking down of staring lights on a polished boot or similar surfaces, and the removal of any glaring defects which were in violation of natural or artistic truth. This "correction" is, we apprehend, applied as a simple duty and artistic matter-of-course to the majority of the portraits. Take an example of considerable touching in this way. The portrait of the young lady whose sitting we described in our last, although an excellent photograph as well as a charming picture, nevertheless required "correction." The white lace, to which we before referred as giving a "spottiness" destructive of pictorial effect, we found, in the finished print, was toned down with the pencil, and the obtrusive spotty lights it caused are sobered into harmony. A blue ribbon which tied the hair, and by its position caught the strongest light, and so became in the negative a mere white patch, is in the print touched to a quite delicate tint, which does not disturb the repose of the picture. The eyebrow, which in nature was very light in colour, and not very strongly marked, is scarcely indicated in the photograph; this, therefore, is strengthened. The gradations in the flesh are slightly blended by very delicate touches. No part of the picture is covered over and hid as in "worked-up" pictures; but various parts are ameliorated by the treatment which the picture has undergone, and without which it would have been imperfect as a work of art. And whilst nothing is added by this treatment to the admirable pose, the fine composition, the richness and solidity, yet it is, on the one hand, freed from offensive staring lights which marred the general effect, and, on the other, it has received some details belonging to the model, although omitted by photography, which add to natural and pictorial truth.

Conscious as we are that it is to artistic skill rather than to the materials used, we feel very diffident in asking questions as to processes and apparatus, but all we ask are frankly answered. The collodion used is simply bromo-iodized collodion, made by M. Salomon himself, as almost every photographer in Paris makes his own collodion. There is nothing peculiar in the silver bath, we are told: it is an ordinary urtrate bath, slightly acid. An iron solution is, as we have said, used both for development and intensifying, and a cyanide of potassium for fixing. The advantages of retouching the negative are not made available; but in many instances, where the face is very soft, a little pink colouring matter is placed at the back of the plate so as to slightly retard the printing in that part, and give a little more vigour to the lights.

A fifteen per cent. printing-bath—that is, a little over a 70-grain silver solution—is used. The albuminized paper is generally a commercial sample, although it is sometimes prepared in the establishment. The ordinary acetate toning-bath is used. Beyond the careful use of these things, there is no other aid to the perfect printing which has struck many observers. We examined prints in the washing-trough, which strike us, as much as the finished prints, with extreme purity of the whites, and suggest to us the extreme care which is evidently taken to keep the paper from the

light, a thing sadly neglected in ordinary printing. The washing-trough is arranged so that each print shall hang vertically in the water, so as to secure practically a continued drawing process during washing. The prints, after mounting, rolling, and "correcting," when necessary, are treated with wax, and then at once placed under glass. Each portrait is treated as a work of art which it is worth preserving.

In a conversation on the lens used, we learn that the old Hermagis was a careful selection from six of the same make, tried at the time. First, the whole were tried on one object, and the two giving the best result selected. These were then tried together and the best selected, for testing again with each other; and, to adopt the simile of M. Salomon, all the lenses, like horses on a race-course, having started fair, one after another dropped out of the running, until one alone was found much superior to all the rest, and this one was retained. The lens is, undoubtedly, capitally suited to the class of work done; but M. Salomon craves for something better, especially for more depth of focus, and intimates that he had recently tried one of the lenses celebrated for that quality, of an English maker. He found it in a single trial decidedly more rapid than the French lens, and anticipated good results when he had time to test it more fully.

Before leaving M. Salomon's studio, we may briefly refer again to the pictures produced there, and to the singular excitement they have caused amongst all interested in photography. As we have before stated, M. Salomon confines himself to working on one size of plate, which is 27 centimetres by 21 centimetres, or  $10\frac{1}{2}$  inches by  $8\frac{1}{4}$  inches. The proportion of the sitter included on this plate is, as a rule, about three-quarters of the figure, or a trifle more; in one or two instances only we have seen full-lengths, and in no case a large head and bust, nor, in any case, vignettes. The size of the head, in different examples, varies from an inch and a quarter in length to two inches. The prevalent characteristic of the pictures is massive grandeur, at least seven-eighths of the picture, as a rule, consisting of shadow or dark mezzotint, in which, however, there is no blackness, but a rich depth and transparency rarely seen in photographs. The amount of pure white in each picture is exceedingly small; and we do not find it occurring in any instance covering a space larger than a peppercorn, without gradation. Even in white linen, such as the cuff or collar of a shirt, we find detail and gradation, whilst in no instance do we find a fault, too common in many photographs, that the broad lights of flesh, such as a forehead or back of the hand, is represented by bald patches of white paper, undistinguishable from the tint of the linen. Many of the old painters were in the habit of introducing a little white in a painted portrait as a test of the purity and truth of their colour in flesh. M. Salomon is evidently fond of the same practice as a test of the truth of the texture and tint of his flesh in monochrome, and we almost invariably find a little touch of pure white in a linen or lace cuff next the hand, or in a collar next the face, giving great value to the tender gradations and modelling of the flesh. The breadth of shadow which prevails in his pictures is obtained by various means when it does not happen to exist in the costume of his sitter. Lace and velvet draperies of various kinds are at hand, and frequently used as adjuncts to the ordinary apparel of the sitters; curtains, table-cloth, column, a dark background—almost invariably placed so as to yield in itself light and shade, and hence the effect of relief, space, and atmosphere—are all made subservient to the characteristic pictorial effect. Although so little white is found in the pictures, they are generally distinguished by great luminousness and brilliancy, every shadow being rendered transparent by low lights in proper subordination. This is assisted by the rich warmth of tone which, with singular uniformity, prevails in the pictures, no cold or slaty effect being seen in any of the examples. Great variety of effect in the pose and arrangement prevails; but in all cases there is definite

intention manifest, and certain carefully considered plans of composition, and in all cases a perfect balance, both of lines and masses, is preserved. A standing position is evidently in favour with M. Salomon, and a profile, or five-eighths view of the face, is often made very effective in his hands.

A careful analysis of many of his pictures would be very instructive: we mean a pictorial analysis or examination of the plan of composition, not an analysis of the physical materials of which the picture is formed; as it is undoubtedly to the art excellence which the pictures owe their superiority. Of the fact of this superiority no doubt can exist. It is proclaimed by the large demand for them at high prices. Some time ago it was stated that M. Salomon had produced over fifteen thousand negatives; and as each negative represents four pounds sterling, and every duplicate print one pound, it is manifest that a large public appreciation of the superiority of the prints must have prevailed. It is not less proclaimed by the eager interest with which varied theories have been put forward to account for the superiority, and by the envy and jealousy which it has excited. "Dodges" of various kinds have been the common explanation; secret modes of manipulation; the use of a peculiarly coloured collodion; working on the negative; a secret printing process; masking and sunning down; and, above all, elaborate retouching, or working upon each print, and producing a monochrome painting instead of a photograph. The eagerness with which many have endeavoured to prove that photography was incapable of producing the results has been little creditable to their faith in their own art; and the bitterness with which others have endeavoured to show that whatever photography could do, these, at least, did not owe their superiority to photographic excellence, would have been amusing if it had not had something more of sadness in its suggestion. These are they whose

"Low desire  
Not to feel lowest makes them level all:  
Yea, they would pare the mountain to the plain,  
To make an equal baseness."

And they who,

"If they find  
Some stain or blemish in a name of note,  
\* \* \* \* \*  
Infat themselves with some insane delight."

It seems to be overlooked by many that all the secrets and dodges in the world would not account for the artistic qualities in which the superiority lies; that retouching would not account for the greater part of the characteristic excellence of these pictures, which consists chiefly in the pictorial composition, and, so far as it is of a technical kind, is found rather in the rich masses of transparent shadow of which the bulk of each picture consists, than in any other especially photographic peculiarity.

We have insisted, from time to time, upon the fact that it is to art qualities chiefly the superiority is due, because we believe it is true, and because we are very anxious to impress the importance of art culture upon photographers. We have insisted that this excellence was not due to dodges or secrets, because we were anxious that our readers should not be, to use a colloquialism, placed on a false scent, and so inevitably miss the chance of improvement. We have insisted, not that the pictures were in all cases untouched, but that it was not to retouching that they owed their peculiar effectiveness, because such an impression was mischievous and misleading.

It may be desirable, in conclusion, to correct another error which has been made in one or two quarters, namely, that likeness to the original is sacrificed to pictorial effect. In this matter we can only speak of the cases we know. Of half-a-dozen portraits of members of our own family and personal friends we possess, in each instance they are characteristic and pleasing; as perfect as likenesses as they are effective as pictures; eliciting, by common consent of all who see them, the acknowledgment that they are the most satisfactory likenesses which the originals have had taken.

We take leave of M. Salomon's studio, satisfied that the

pictures he has produced and exhibited cannot fail, notwithstanding the discussions and jealousies they have excited, to give an impulse to artistic portraiture, by showing that a much higher standard is possible than that usually attained. For our own part we have been at once gratified and instructed by our examination of his pictures, and by the repeated visits to his studio; and we have here pleasure in expressing our obligations to M. Salomon for the ready liberality with which he has placed every facility in our way for affording the fullest information to our readers, and for the kindly courtesy and pleasant welcome extended to ourselves personally on every occasion we have had the pleasure of seeing him.

### Critical Notices.

#### THE PHOTOGRAPHER: A Manuscript Magazine.

THE last number of this revived amateur magazine, to which we referred some weeks ago, contains some examples of the comic lyrics occasionally sung at photographic festivals. The story of "Mr. William Baker, a Carte-de-Visite Taker," is told, for which we may, on another occasion, find space. We now quote a song which was prepared for the last South London Dinner, and sung amid much applause and laughter. As our readers will see, it relates a photographic episode in the life of a popular convivial monarch.

##### KING COLE TURNED PHOTOGRAPHER.

I.  
Old King Cole was a merry old soul,  
And a merry old soul was he;  
But he gave up his pipe, and he gave up his glass,  
To take up with photographicie.  
For one summer's night he had a great fright,  
And a very queer dream had he,  
That one Jabez Hughes stuffed the Photographic News  
Into his cerebral cavity.  
And he went raving mad, crying, "Oh! that I had  
A taste for photographicie."

II.  
Old King Cole was a merry old soul,  
And a merry old soul was he;  
"Oh, bother my pipe!" said he, "bother my glass!  
And bring me my cameras three."  
Each camera had a fine lens,  
As fine as a lens could be;  
'Twas made by a man who was named Voightlander  
And Company,  
With a spherico-concave-convex curve,  
And an aperture six foot three.

III.  
'Twas worked by steam, though strange it may seem,  
And lighted by electricie,  
And sixpence a day kept the bath in full play,  
While collodion was generated free.  
It dipped its own plate, and posed those who sate,  
All by rackwork machinerie;  
And it washed and developed, and in passe par tout enveloped,  
A marvel of photographicie.

IV.  
Old King Cole was a merry old soul,  
And a merry old soul was he;  
"I want a carte-visite (my camera, where is it?)  
Of my first Lord-in-Waiting," said he.  
He put him on a chair, and he fixed him there,  
As tight as if screwed by the knee;  
But the focus was so strong, it dragged him along,  
And suspended in mid air was he.  
"Oh, there's none anywhere," says he, "can compare  
With the wonders of photographicie."

V.  
He next tried its power on a passing rain shower;  
But so sharp was its efficacy,  
That the big drops of wet through the thick lens would get,  
And a small bit of thunder strained free.  
A baby, one day, whom he tried to portray,  
As plump as a baby could be,  
Was found squeezed flat, and as black as your hat,  
On the ground glass, d'ye see.  
"Oh, there's none anywhere," says he, "can compare  
With the wonders of photographicie."

##### VI.

If a landscape scene he tried to get in,  
With the flocks roaming over the lea,  
You could hear the sheep bleat when you looked on the plate,  
And the cows lowed as plain as could be.  
And, once, when his art he tried on a cart,  
With a horse rather frisky to see,  
He was done with such tact, that the horse kick'd in fact,  
And from negative nearly got free.  
"Oh, there's none anywhere," says he, "can compare  
With the marvels of photographicie."

##### VII.

If a man and his wife, by chance had a strife,  
And the instrument near them placed he,  
You could hear naughty words 'twixt the lens and the boards,  
And their thumps 'gainst the side most plainlie.  
But the worst that befel was most wondrous to tell,  
When a battle he tried to display,  
For the gunpowder smoke his best Voightlander broke,  
And blew the whole camera away.  
"Oh, there's none anywhere," says he, "can compare  
With explosions in photographicie."

##### VIII.

So Old King Cole, that merry old soul  
(For a merry old soul was he),  
Said he: "I've had quite enough of this troublesome stuff,  
And I'll now give up photographicie;  
I've blacked both my thumbs, and filled my albums,  
And I've spent no end of monie;  
For the rest of my life I'll give up toil and strife,  
And stick to my fiddlers three;  
Though there's none anywhere that I know can compare  
With the marvels of photographicie."

### ECHOES OF THE MONTH.

BY AN OLD PHOTOGRAPHER.

THE LATE MR. THURSTON THOMPSON—APPOINTMENT OF PHOTOGRAPHER AT SOUTH KENSINGTON—FIRE PROOF ROOMS FOR NEGATIVES, ETC.—THE OLD TONING AND FIXING BATH—COLLODIO-CHLORIDE PROCESS—MR. McLACHLAN'S DISCOVERY—DISTILLED AND COMMON WATER—SEL CLEMENT—SALOMON'S PORTRAITS—SOCIETIES.

YET another of the foremost rank in photography has been numbered with the men that are gone. Mr. Thurston Thompson was little known, personally, to the public, being a modest and most unobtrusive gentleman; but he was one of the men of the highest culture in connection with our art, and of exceedingly fine taste; and few men could have been so thoroughly well qualified for the duties of Photographer to the Science and Art Department as he. His work in reproducing the valuable contents of the Museum at South Kensington must have been well nigh done, as upwards of ten thousand negatives, I understand, have already been secured in that department. As was not unnatural, there were several candidates anxious to fill the position made vacant by the death of Mr. Thompson, and I understand that another gentleman bearing the same name, but no relation, has received the appointment. Mr. Stephen Thompson, a photographer of much taste and skill, will henceforth undertake the foreign photographic work for the department; the work at home will be done, as it has been for some time past, by Messrs. Cundall and Fleming.

A disastrous fire in a photographic establishment is fortunately not of very common occurrence. That which recently took place in Mr. Claudet's studio, in Regent Street, however, suggests some startling reflections as to the importance of fire-proof rooms in photographic establishments. Upwards of twenty thousand negatives are stated to have been destroyed, much of the damage being caused, I am told, by water. This is a serious matter; for, in a certain sense, the negative may be said to be held in trust by the photographer for the benefit of the public. The sitting having been accomplished and the price paid, the public believe that henceforth they can go and have prints when they require. The ownership of the negatives is a point which has not yet been authoritatively determined.

Some affirm that the price paid at first covering the cost of the production of the negative, it is legitimately the property of the sitter, as a card plate belongs to the customer after he has paid the price for engraving it. But, be this as it may, it is left in the hands of the photographer under an impression that he can at any time command prints from it without paying the first cost of production again. Thus a quasi obligation is laid on the photographer, for the sake of the public, as well as himself, to preserve the negatives with extreme care. How far fire-proof rooms would preserve negatives amid the great heat of a burning building remains a question to be determined. There is another class of property to be considered under such circumstances. Whilst I was looking at the scene of Mr. Claudet's fire, I noticed a lady and gentleman enquiring after a family portrait, in the shape of an oil painting, which had been left to copy; and it, with many more such, had perished in the flames, an irreparable loss. These are the common risks of life, it may be said; all valuable things are liable to destruction. True; but just in proportion to the possibility of loss, and to its irreparable character, becomes the importance of safe-guards; and it appears to me that, from the importance of preserving these things, it may be worth a thought, in building large and important photographic establishments, as to whether a fire-proof room ought not be secured for the safe keeping of negatives and other important matters.

The question, "Do you think that we shall return to the old toning and fixing bath?" has been asked in my presence repeatedly lately. Almost all photographers speak with a certain degree of regretful affection of the old method. When it was abandoned it was in the firm hope of obtaining greater permanency; but photographers now-a-days are often tempted to ask, Has the greater permanency been secured? The question was boldly stated by Professor Towler in your columns recently, and it is one, I think, which will well repay discussion. For my own part I can simply say, at present, that I have prints in my possession toned and fixed considerably upwards of a dozen years ago, which are still free from signs of fading.

A print I have seen, by Obernetter's modification of your collodio-chloride process, is exceedingly fine, and one cannot but wonder that a process so capable of fine results is not more practised in this country, where it was first introduced. English photographers are singularly conservative. Albuminized paper is the recognized material for prints, and modified silver processes and carbon processes alike fail to dislodge it.

Mr. McLachlan's announcement is a startling one. Absolute certainty of the chemical conditions which will secure the highest success, absolute certainty of maintaining these conditions: what more in this direction can we possibly require? I must confess that it is a little hard on photographers to place each in the position of Tantalus for six months, with the cup just within, but still beyond, reach of his thirsty lips. Some I have heard disposed to regard the announcement as a practical joke, and others treat it as gasconade; but, after all, if Mr. McLachlan have discovered the actual nature of the change effected on the sensitive film by light, there can be little doubt that such a knowledge will very materially simplify the conditions of success. Mr. McLachlan states that he has discovered the change to be a chemical one: this determined, the causes which retard or facilitate or otherwise affect the chemical action may be easy to state. Altogether, I am disposed to hope that Mr. McLachlan's announcement bodes good to photographers.

The question raised by Mr. Cherrill as to the use of common water in place of distilled water is an interesting one; but it must be owned that his proposition is somewhat audacious. So much stress has always been laid on the use of distilled water in photography, that a proposition to throw it aside altogether seems to strike at the very basis of our photographic faith. There is a daring independence in the

notion which is very attractive, and as Mr. Cherrill is known to be an excellent photographer, it may be taken for granted that the idea has been both well considered and tried before it was committed to the public. For printing-baths, toning-baths, developing-solutions, &c., I have long used river water myself; but I must confess that I should hesitate at present to use it for my negative-bath, or for the first washing of dry plates. I am open to conviction, however, and I presume that we have not yet heard the *dernier mot* on the subject. The difficulty which strikes me most is the great variety in quality of what is termed "common water," which may mean almost anything, and contain almost any impurity without exciting suspicion, so long as the clearness and brightness of the water is not destroyed.

Has any of your readers tried the "Sel Clemeut, or Preservative Nitrate of Silver"? Something like eight years ago, I remember, a "photographic ink," to supersede nitrate of silver, was introduced in Paris, which turned out to be, on examination, nitrate of silver and nitrate of potash. The new salt is, I am informed, nitrate of silver and nitrate of magnesia. The compound will, I believe, be useful in printing; but whether economical or not is another question, which can only be fairly determined by trial.

The controversy on the subject of M. Salomon's prints still keeps cropping up afresh. Many photographers are quite satisfied as to the means of obtaining them; but they all abstain, with singular self-denial, from putting the means into practice, and producing similar pictures. An "analysis" of these pictures, published in a contemporary, and signed "Scrutator," was very amusing. If the statements made were true—namely, that on sponging a print, and removing the retouching, a poor, hard, black-and-white picture only was left—it is obvious that they required the guarantee of a responsible name, instead of a mere *nominis umbra*, and that, if the writer did not care to divulge his name, he should have sent the proofs of his statement, so as to secure the endorsement of the Editor. As the matter stands, the statement appears to me without any value whatever. An opinion or an argument may be as valuable when put forth anonymously as when guaranteed by a name; but a statement of alleged facts, especially if those facts impeach the good faith of another, is worse than worthless when put forth anonymously. If the statement be true it is of little weight, as no one will be so foolish as to draw general conclusions from such narrow and insufficient premises as the examination of a single picture, which, by the way, it is insinuated, was one of the prints (the lady with riding whip) exhibited by the Editor of this Journal at the late exhibition in Conduit Street, and he ought to be able to throw some light on the story.\* There is one important idea in connection with this subject which should be borne in mind: as much of artistic culture consists in acquiring the power of seeing, it is manifest that the incapacity of producing such pictures as those in question is much dependent on the incapacity to perceive the real sources of their beauty; and although executive skill is necessary, as well as perceptive and conceptive power, to the artistic faculty, yet once a photographer has made himself master of the sources of superiority in these pictures, he will have progressed considerably in the direction of producing something like them.

At the Societies some interesting subjects have been discussed. The North London meeting, following on New Year's Day, consisted only of the Chairman, the reader of the paper, two reporters, and one member to form the audience. The discussion on the paper, which was by Mr. Dunmore, on art subjects from a photographic point of view, was therefore postponed. At the Parent Society, Mr. Spiller read one of those valuable papers, full of valuable information on the chemistry of photography, with which his name is generally associated. At the South

\* Neither the lady with the riding whip nor any of the pictures we exhibited in Conduit Street have been out of our possession since, nor have they been subject of any such "analysis."—Ed.

London Society, Mr. Johnson read a capital paper on clouds in landscapes, and a very interesting discussion followed. At the Provincial Societies nothing very noteworthy has occurred.

### THE ACTION OF OZONE UPON THE LATENT PHOTOGRAPHIC IMAGE.

Dr. PIERSON, in his correspondence with our Paris contemporary, mentions that Dr. Emerson Reynolds has just completed a series of experiments calculated to throw some additional light upon the nature of the latent photographic image, and aid in bringing to a termination the discussion which has been going on for several years in reference to this subject. Dr. Reynolds conceived the idea of studying the action of ozone upon the latent image—that is to say, upon the image before development—and he has communicated the results of his researches to the Dublin Chemical and Philosophical Club. He found that in submitting the latent image to the action of ozone the picture disappeared completely; not only could no image be developed, but it was possible to obtain a second image upon the same plate on replacing the latter in the camera.

The author remarked (and it seems to us with much truth) that this experiment utterly destroys the idea of a physical action, and completely refutes the arguments of those who pretend that the first influence of the luminous rays is to bring about a molecular change whence results the latent image, which is afterwards developed by means of chemical agency. According to Dr. Reynolds a chemical action is set up from the commencement, and the latent image is therefore not due to a physical change, but is purely the result of chemical decomposition.

This action of ozone upon sensitive plates, and its presence in greater or less quantities in the atmosphere, suggested to the author the idea that the many discussions which have lately taken place with reference to the time that dry plates will retain their sensitiveness may thus be explained; in fact, plates ought to exhibit a greater or less degree of sensitiveness, according to the amount of ozone existing in the atmosphere on the day of their exposure.

The ozone—or, rather, the oxygenized air—employed in these experiments, was obtained in two different manners, both descriptions furnishing identical results. The one kind was obtained by passing atmospheric air over phosphorus half covered with water, and the other by means of the silent electric discharge—that is to say, by attaching one of the platinum wires of the reservoir to the conductor of an electric machine, the handle of which was slowly turned, the other wire being put to earth.

### VITRIFIED INDIA-RUBBER SHEET,

*Applicable for the Transfer of Films, to Printing Transparent Positives, and to the Production of Carbon Photographs.*

WE learn, from the statement of M. Ernest Lacan in the *Moniteur*, that M. Marion is about to introduce into commerce a new material calculated to render important services to the photographer. According to information borrowed from a pamphlet entitled *Notes Photographiques de 1868*, which is shortly to be published, this new material appears to hold an intermediate position between paper and glass, having the suppleness of the former combined with the transparency of the other, without possessing its fragility. The purposes to which such a material may be put, as a support for collodion, either as a basis upon which to pour the sensitive solution, or for transferring the film from a glass plate, are at once easily understood. It is very simple and easy to manipulate, and in many ways susceptible of advantageous employment in the studio, and more particularly when travelling.

M. Marion is sanguine that it will be possible to produce a photographic image upon the film itself, and in this case

nothing would be simpler than to supply it to operators in a sensitized condition.

The method of applying the sheets of vitrified india-rubber is as follows:—

A varnish of a special character is poured over a glass negative, varnished or not as the case may be, and the sheet of rubber placed thereon; when perfectly dry the plate is plunged into water, and in a very short time the film will abandon its previous support and adhere to the new one. Pictures transferred in this manner may be kept in a box or portfolio until required for printing, and will be found to yield the most excellent pictures, remarkable both for clearness and harmony of tone.

The carbon process will certainly find in this material an element specially calculated to simplify and vulgarize the method. In fact, the most simple mode of proceeding will be to use the rubber film as the basis of the coloured pigment composition, which is then exposed under a negative, the prepared side outwards. After developing the image in warm water it is mounted on cardboard, face downwards, so that the transparent film of rubber keeps the picture perfectly even, and likewise serves as a protection to it; or, M. Marion believes it will even be possible, after the picture has been mounted, to detach the india-rubber film, which may afterwards be used over again for the same purpose. In the mean time, however, he will confine himself to the manufacture and supply of ordinary transparent india-rubber sheets capable of employment in any way that the operator may judge most fit; and it is certain that in its present condition the material will be applicable to many purposes in the different branches of the art.

### HYPOSULPHITE OF AMMONIA AND THE MIXED TONING AND FIXING BATH.

BY NELSON K. CHERRILL.

PERHAPS there is no subject of more universal interest among photographers than the improvements made from time to time in the various methods of printing. All photographers look for permanence in their work, and all hope to obtain it in some way or another. Some have tried, in many ingenious ways, to mend the old paths, and improve the silver printing which has been so long in vogue; while others have made for themselves new paths, and have sought for permanence in the known stability of carbon and its application to photography.

It is, I think, allowed on all hands that, for many purposes, silver printing is most important, and its improvement will always be a matter of great interest and utility. I have, for a long time past, been much in favour of carbon printing, as I have always said, for “one’s best work;” but to any one who has experimented much in carbon it is manifest that none but first-rate negatives must be used in carbon printing; and so, whilst it is often necessary to print from a negative not quite up to the proper standard for carbon, and whilst a cheaper form of printing than carbon is required, and also as long as, for a certain class of subjects, the peculiar richness and glaze of albumen paper is thought desirable, there can be no doubt but that silver printing will maintain a high position, even though some few men may desert it in favour of the more permanent and artistic carbon printing.

Whatever may be the feelings of the photographic public on the comparative merits of carbon and silver printing, there can now be no doubt as to the mind of the general public in the matter. “If,” say they, “carbon is permanent, give us carbon.” When photographers are in the position to say: “Our silver prints are as permanent as our carbon ones”—if ever they be in that position—of course it remains to be seen what the public will say respecting the comparative merits of carbon and silver printing. Now they know, by experience, that silver prints, as usually done, are anything but permanent.

The two main causes of want of permanence are pretty well known: one is the imperfect action of the fixing bath, and the other is the imperfect washing of the prints after they are fixed. One of them is a chemical difficulty, and the other a mechanical one. It is of the chemical difficulty that I am about to speak.

Mr. Spiller, a gentleman to whom all photographers are indebted for his patient investigation of the subject of imperfect fixation, has told us of a plan by which, in his opinion, this chemical imperfection can be done away with. This discovery, if it be substantiated by further experiment, is one of very great importance, and one to which too much attention cannot be paid, because, if we can be rid of the chemical element of decay in our silver prints, I look upon the mechanical question of washing out the hypo as a matter of comparatively easy accomplishment. Mr. Spiller recommends the use of hyposulphite of ammonia to supplement the action of the hyposulphite of soda.

When I read Mr. Spiller's paper (read before the London Photographic Society), a thought struck me that possibly the same thing might be done in some other way. I do not know if I am right, but will explain. Mr. Spiller says: Add chloride of barium to hyposulphite of soda, and you will have formed hyposulphite of baryta; add hyposulphite of baryta to sulphate of ammonia, and you will have hyposulphite of ammonia. Now, it struck me, *why not* add hyposulphite of soda to sulphate of ammonia, and why should not these form, in some measure, the hyposulphite of ammonia. I will give it in symbols. Thus

And

Now, it appeared to me that perhaps, if hyposulphite of soda were added to sulphate of ammonia, much the same thing might occur. Thus

so that, by adding some sulphate of ammonia to the ordinary hypo bath, a certain proportion of hyposulphite of ammonia might be formed in the solution.

Some similar result, it struck me, might be obtained by adding the carbonate of ammonia to the fixing bath (as before recommended by Mr. Spiller), and then, perhaps, the advantage gained by so doing might result from the formation of a proportion of hyposulphite of ammonia. Be this as it may, I put my idea to the practical test, and send up by book post, with this paper, the results I obtained.

As it seems to be stated on authority that no gain in permanence *ought* to be obtained in separating the toning and fixing solutions, my experiments were directed to the addition of sulphate of ammonia to the bath, recommended by Professor Towler in the News a week before Mr. Spiller's paper.

After a careful consideration of the matter, I resolved to make the bath for toning and fixing as follows:—

Water	...	...	8 ounces
Hyposulphite soda	...	...	3 "
Sulphate ammonia	...	...	2 drachms
Acetate soda	...	...	1 drachm
Chloride of gold...	...	...	5 grains,

mixed in the manner recommended by Professor Towler. The prints were plunged in this solution straight from the printing-frame, without any previous washing. They toned beautifully, and it was manifest that, after a little practice,

any tone could be obtained with great ease. The reduction in tone was not so much as with the ordinary alkaline bath, but rather more than with sulphocyanide toning. After fixing, the prints were removed to a pan of water, and washed in the usual way. One of the prints had come to the surface of the fixing bath, and had consequently become spotted, owing to the unequal action of the solution. This spottiness subsequently served to show the comparative effect of the hydrosulphate of ammonia on those parts which had a shorter time in the fixing bath than usual. To test these prints as to their chance of permanency, I took a solution of hydrosulphate of ammonia in water, and treated them with it.

Of those I send in the separate parcel, the pantaseopic picture, with the brown stain in the middle, is one done about three years ago in the ordinary manner. It shows, as you see, no sign of fading or of yellowness in the sky; or, rather, it did not when I began to experiment with it. A few drops of the hydrosulphate solution, poured in the centre, showed at once the brown stain now seen there. At the same moment I poured on the sky of the other landscape enclosed—one done with the new bath—some of the same solution of hydrosulphate: you will see what a very slight effect it has had. The brown stain is not by any means so apparent in the one by the new bath. To show that the age of the former print had nothing to do with the formation of the stain, I also tried a much more recent silver print, also in very good condition, and with just the same effect; viz., the formation of a deep brown stain in the whites where the hydrosulphate solution touched it.

The very slight stain in the sky of the picture done in the new bath seems to me much more due to the discolouration of the silver present in the delicate tint of the sky than to any silver present in the whites; and this position is confirmed by the little portrait of a gentleman, in which part of the paper was marked by the black paper in the printing. In this case, though the hydrosulphate solution (of the same strength as before) was in contact with the print for nearly a quarter of an hour, yet it will be seen there is no yellowness or discolouration upon the white part of the picture, which remains almost, if not quite, as pure as it was before the application. The colour of the silver forming the picture has, however, suffered from the prolonged application of such a severe test.

I merely mention and exhibit these results that those who take an interest in them may form their own opinion of their merits, and may judge for themselves of their bearing on the question at issue—the perfect fixing of silver prints. The matter is one, as Mr. Spiller, and, indeed, as all experimenters justly observe, for “further investigation.”

I propose to continue my experiments, and, should they issue in any further successful result, shall be happy to send you a further communication on this subject. In the meantime, I shall look forward with much pleasure to seeing your opinion of these experiments expressed in the News.

## PICTORIAL EFFECT IN PHOTOGRAPHY;

BEING LESSONS IN

COMPOSITION AND CHIAROSCURA FOR PHOTOGRAPHERS.

BY H. P. ROBINSON.

CHAPTER 2.

“This laborious investigation, I am aware, must appear superfluous to those who think everything is to be done by felicity, and the power of native genius.”—*Sir Joshua Reynolds.*

“Let me see, let me see, let me see!”—*Shakespeare.*

It is an old canon of art that every scene worth painting must have something of the sublime, the beautiful, or the picturesque. By its nature, photography can make no pretensions to represent the first, but beauty can be represented by its means, and picturesqueness has never had so perfect an interpreter. The most obvious way of meeting with

picturesque and beautiful subjects would be the possession of a knowledge of what is picturesque and beautiful, and this can only be attained by a careful study of the causes which produce these desirable qualities. He who studies the various effects and character of form, and light, and shade (to a photographer the addition of colour would only be complication), and examines and compares those characters and effects, and the manner in which they are combined and arranged, both in pictures and nature, will be better qualified to discover and enjoy scenery than he to whom this study has never appeared necessary, or who looks at nature alone without having acquired any just principles of selection. However much a man might love beautiful scenery, his love for it would be greatly enhanced if he looked at it with the eye of an artist, and knew *why* it was beautiful. A new world is opened to him who has learnt to distinguish and feel the effect of the gorgeous harmonies that nature presents in all her varied aspects.

Take an illustration of how much more an acute observer of nature must enjoy than the dull man who jogs on through the world with his eyes open but his mind blind. Can it be doubted that Shakespeare more infinitely enjoyed the amusement he derived from his study of character than common observers? Combinations of incidents and characters must have struck him much more forcibly, and must have afforded him keener enjoyment than they would those who had not the capacity of seeing and appreciating the humours of the times in which they lived. His works point out to us many scenes that would escape us in real life. So also the trained artist will discover and reveal beauties that others pass by without notice, in our walks abroad and in our every-day existence. How often does it happen that a photographer will take his camera and dozen dry plates to a district he has been recommended to visit because it contains so many picturesque objects and artistic bits, and has returned at night unsatisfied and gloomy, with "no game in his bag," declaring the place dull and uninteresting, without a single object worthy of his attention; again, another photographer, who, like Beatrice, "can see a church by daylight," but little else, will walk through the land photographing every object, so that it is an object, he meets with. But then what he means by an object is something very definite; it must be a castle, or abbey, a stone cross, or mansion—something you can "put a name to." It is of no consequence to this collector of negatives whether his subject has anything in it capable of artistic treatment, whether a few yards to the right or left would improve the effect, or whether a little more sky or a little more foreground would increase or diminish the apparent size of the subject he is about to secure; his only anxiety is that the house or castle he is photographing shall come in the middle of his plate, and that nothing shall come in the way of his getting a good map of its elevation. This is no fanciful picture I am sketching, but I have so many originals for it in my mind's eye that it can scarcely be called the portrait of an individual. Yet another photographer will scarcely care where he goes; he has learnt to select, and finds pictures everywhere. He does not do this by instinct or any inborn faculty; he has had to acquire his knowledge; he has learnt to know what he wants, and picks it up the moment it is before him. It must not be inferred, from what I have just said, that because art has to be learnt I consider it possible for all to learn alike. It is not possible for one in a thousand to attain a perfect knowledge of art; but it is certain that all, especially those whose instincts have turned them to a kindred study like photography, may learn sufficient to save them from making any very serious blunders in their works. All men have to learn. "Art," as Sir Joshua Reynolds has said, "is not a divine gift." The power of acquiring it perfectly undoubtedly is.

These observations may appear trite, but they are the keynote of all I have to say in future chapters. I wish to show that it is the photographer's business to *see*; to do which he must learn to see, that by seeing he may appreciate, and that the power of seeing may be, as it were, artificially

cultivated by the study of those rules and axioms which have guided the greatest painters, sculptors, and architects, in the production of their finest works.

But, before I proceed, I must warn my readers against a too close study of art to the exclusion of nature and the suppression of original thought. Whoever studies art alone will have a narrow, pedantic manner of considering all subjects, and of referring them to this or that style of composition, or this or that order of picture. This class of student looks at nature only through the medium of famous painters' pictures; a calm sunset is always a Claude; anything wild or confused is Turnerian (in his last period; it shows knowledge to speak of the "periods" of a master). "What a delicious Wilson or Ruysdael!" one will say as he looks at a waterfall; "Quite a Landseer!" another will exclaim at the sight of a sheep-dog or deerhound; and so on. Nature can only remind them of some class of picture. This is a perversion of study, and tends to degrade nature to the level of her imitators, instead of assisting to elevate her students to the level of the humble distance from her perfections to which it is possible to artists to attain. What I want here to impress is, that art should be a guide only to the study of nature, and not a set of fetters to confine the ideas or to depress the faculty of original interpretation in the artist, whether he be painter or photographer; and a knowledge of the technicalities of art will be found the best guide.

There is a tendency amongst young artists to despise rules, and to trust to instinct and a feeling for art; but it is not only well to do right, even if that were possible, by instinct alone, but it is also pleasant to *know* you are doing right; and, although it is not well to curb rising genius, a knowledge of principles which, from their universal adoption for ages, must be sound, must be an addition to the powers an artist, in whatever material, has to bring on his subject. Sir Joshua Reynolds, in his sixth discourse, has some excellent remarks on this subject, which are much more forcible than anything I could hope to say myself.

"It must of necessity be, that even works of genius, like every other effect, as they must have their cause, must likewise have their rules; it cannot be by chance that excellencies are produced with any constancy or any certainty, for this is not the nature of chance; but the rules by which men of extraordinary parts, and such as are called men of genius, work, are either such as they discover by their own peculiar observations, or of such a nice texture as not easily to admit being expressed in words, especially as artists are not very frequently skilful in that mode of communicating ideas. Unsubstantial, however, as these rules may seem, and difficult as it may be to convey them in writing, they are still seen and felt in the mind of the artist; and he works from them with as much certainty as if they were embodied, as I may say, upon paper. It is true these refined principles cannot be always made palpable, yet it does not follow but that the mind may be put in such a train that it shall perceive, by a kind of scientific sense, that propriety which words, particularly words of unpractised writers such as we are, can but very feebly suggest."

Having now pleaded, where no pleading should be necessary, that artistic knowledge is essential to the photographer, I shall aim, in succeeding chapters, to become more specifically practical, and endeavour to give my readers some ideas of those forms of lines, and of masses of light and shadow, that constitute composition in art. These forms, which produce balance, unity, and harmony, may often seem intangible, and the student may be tempted to ask—

"If shape it might be called, that shape had none  
Distinguishable in number, joint or limb,  
Or substance might be called that shadow seemed,  
For each seemed either!"

But to the instructed eye each intangible line, and light, and shadow, plays its definite part in forming a perfect composition.

## THE MAGIC LANTERN AND PHOTOGRAPHY.

BY JAMES MARTIN.

## No. 5.

WHEN the pupil has succeeded in obtaining a clear, firm, and true outline, the glass on which he has been working may be removed from off the copy. Before leaving this subject, it is as well to observe that, although the outline in the foreground objects may be moderately coarse, it ought to diminish in size as the planes of the picture recede, until, in the extreme distance, it is very fine, indeed; otherwise the aerial effect will be marred, and every object seem as if edged with a black ribbon. This effect is much increased by the great magnifying power of the lenses used in the lantern. Some artists, instead of lampblack, make their outlines of various tints approaching those of the objects to be painted, so that when they are finished they are not seen at all. Having all the colours to be used finely ground, the glass easel erected to a proper angle, with a piece of white paper underneath to reflect the light through the picture placed on, it will be requisite to form a sort of palette, or series of colours, on either a piece of glass about plate size, having a piece of white paper underneath it while in use, or a small earthenware palette, which can be bought of any artists' colourman for a few pence. This will suit the purpose better than anything else, as the real strength of the tints of colours can be easily seen on its white surface when setting your palette. It is best to always place the colours in the same rotation, beginning at the same place, so that you may know readily where to find the colour when wanted. It is usual to place the light and warm colours near the thumb, the darker and colder colours round the rim; therefore the gallstone will be placed next the thumb, then the madder carmine, and lastly the blues. Supposing some pleasing subject is chosen as an example to begin with, containing not too much complication of outline, but embracing as many of the usual features of a landscape as may generally be found in one picture; for instance, the view of the Castle of Chillon, a popular picture for the magic lantern, to which that of the Prisoner of Chillon in the Dungeon makes an exceedingly interesting contrast. The scene opens with a fine terrace or road (edged by a low wall) winding up towards the castle; in the foreground is a picturesque group of peasants; in the middle distance are precipitous rocks, some crowned with fine trees, also green mounts and slopes, gradually descending to a beautiful sheet of water, on the edge of which stands the castle, jutting boldly out and casting its long shadows on the glassy surface, the monotony of which is broken by the appearance of a small skiff gliding onward under its broad white sail; in the extreme distance rise the blue mountains, which, with the summer sky and clouds, form a glorious background to a highly interesting scene. The ingenious pupil will readily perceive that the castle might be replaced by a water mill, an ancient abbey, or chalet; the figures of the peasants by monks, soldiers, sportsmen, or others; yet the general treatment of these subjects may be the same, the outlines and local colour only being altered; and that this picture is not (although very beautiful) chosen for itself alone, but as an example of a class.

## ALBUMEN OPALOTYPES.

MR. WILLIAM BELL, Photographer to the Army Medical Museum at Washington, contributes to our esteemed contemporary the *Philadelphia Photographer*, of which we have received advance sheets, the following formulæ:—

*Albumen for Pictures on Plain Opal Glass and Fine Negatives.*

No. 1.—Albumen ... 6 ounces  
Concentrated ammonia ... 1 drachm.

*Albumen for Pictures on Ground Opal Glass and Strong Negatives.*

No. 2.—Albumen ... 6 ounces  
Chloride of ammonia ... 6 grains  
No. 1 solution of oxide of silver  $\frac{1}{2}$  drachm.

*Solution of Oxide of Silver.—No. 1.*

Ammonia ... 1 ounce  
Oxide of silver ... 40 grains.

Put the ammonia and oxide in a strong vessel, stir well, and add nitric acid until the solution is slightly milky, *but not acid*. Filter, and it is ready for use in albumen No. 2.

*Silver Solution.—No. 2.*

Oxide of silver ... 240 grains  
Concentrated ammonia ... 4 ounces.

Put the ammonia and the oxide of silver in a strong vessel. Stir well, and add nitric acid, C. P., until the solution is *decidedly acid*. Now add 12 ounces of alcohol; filter.

*Silver Solution.—No. 3.*

Nitrate of silver ... 70 grains  
Distilled water ... 1 ounce  
Alcohol ... 16 ounces.

Dissolve the silver in the water, add ammonia until the precipitate first formed is just re-dissolved; pour out one-half into a bottle, and to the other half add nitric acid until it is just slightly acid; mix the two together, and add the sixteen ounces of alcohol; filter.

*Toning Bath.*

Acetate of soda ... 36 grains  
Chloride of calcium ... 36 "  
Chloride of gold ... 1 grain  
Water ... 12 ounces.

*Fixing Bath.*

Hyposulphite of soda ... 1 ounce  
Water ... 16 ounces  
Alcohol ... 3 "

Beat separately No. 1 and No. 2 albumen to a stiff froth; take the settled solution and coat the opal-glass while wet, and stand to dry at this angle  $\searrow$ , albumen side downwards. Dry without heat, and, as the plates keep well, a large quantity can be coated at one time, and, when dry, stored away in a dry place. Take the prepared plate, and dip it into silver solution No. 2 for one minute, then wash it with water until the water flows smoothly from it, drain well, and flow it two or three times with silver solution No. 3, and dry; when dry (if properly done), the surface will be free from any crystallization, and very bright and clear. Print deep. After printing, take the plate and flow it with alcohol, wash off the alcohol with water, tone, fix for three minutes, and wash for one hour. Caution! never take the plate out of the hypo, and plunge it into, or wash it with, a heavy stream of water, but let the water flow gently into the fixing bath. After a little while it then can be washed in a good stream of water. This mode of washing will prevent bubbles forming under the film and the spoiling of the picture. Be sure and have the place where the plates are coated with the albumen perfectly clean. Dust-spots create the troubles most met with.

## Proceedings of Societies.

## LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE Fourth Annual Meeting of this Association was held on Tuesday evening, the 28th ult., the Rev. G. J. BANNER, Vice-President, in the chair.

After the minutes of the previous meeting had been read and confirmed,

The names of the new officers recommended by the Council were read, and the following were elected:—

President—Rev. G. J. Banner; Vice-Presidents—Messrs. O. R. Green and J. Henderson; Treasurer—Mr. Lewis Hughes; Honorary Secretary—Mr. W. B. Bolton; Council—Rev. T. B. Banner, Messrs. C. Phipps, Forrest, W. A. Wilson, Hubback, Atkins, Wharmby, and Guyton.

The usual votes of thanks were conveyed to all the retiring officers, and the Secretary was requested to tender, in writing, a vote of thanks to the Library Committee for the use of the room in which the meetings are held.

The Treasurer's report and financial statement for the year 1867 were then read, showing the Association to be in a very flourishing condition. Having been audited and found correct, the statement was passed.

Mr. FORREST, on behalf of the President, who was unavoidably absent, moved that an alteration be made in Rule X. of the Association, which reads as follows:—

"The Ordinary Meetings shall be held on the last Tuesday in each month with the exception of the following: June, July, and December," the proposed alteration being to leave out the words "the following: June, July, and."

After a little discussion, the motion was carried unanimously.

Mr. MAWDSLEY then moved that in Rule IX. the word "November" be substituted for "January," the object being to change the date of the Annual Meeting from January to November, in order that a correct list of the officers may in future appear in the almanacks, &c., for the current year.

The Rev. T. B. BANNER opposed the motion, and, after a very warm debate, Mr. Mawdsley withdrew it.

It was then proposed by Mr. MAWDSLEY, and seconded by Mr. COOK, that Rule XI. be supplemented by the following:—"Members elected at the October and November meetings to pay no subscription for the current year, but to be considered Honorary Members for the rest of the session."

The motion was passed unanimously.

Mr. EATON CLIFFE was then elected a member of the Association.

The CHAIRMAN introduced the subject of a soiree; and, after a short discussion, it was resolved to hold one, the Hon. Sec. being requested to call a Council meeting at an early date to make the necessary arrangements.

Mr. GREEN exhibited two of his large pictures (24 by 18) of Furness Abbey, one of which was kindly presented to the Hon. Sec. in recognition of his services during the past year. The other, Mr. Green has been good enough to offer as a prize for the best photograph or collection of six photographs, to be exhibited at the meeting in March, the conditions being that the pictures shall be entirely the work of the exhibitor, and shall be taken between the 1st January, 1867, and the day of exhibition.

There were also exhibited some carbon prints by Mr. Cotton, and some stereo pictures in the Isle of Skye by Mr. Hubback.

The meeting was adjourned until the 25th February.

#### OLDHAM PHOTOGRAPHIC SOCIETY.

The ordinary meeting of the above Society was held at Bartlam's Rooms, Horsedgate Street, on Thursday, the 30th ult., the President, Mr. JOHN GREEN, in the chair.

The PRESIDENT, in opening the meeting, said: Gentlemen,—At the formation of this Society it was suggested that it would be more in unison with the feelings of some of the members if the meetings were held elsewhere than at an inn. That suggestion has been adopted, and it is with hopeful feelings for the future that I welcome you to our new abode in Bartlam's Rooms. It must be gratifying to the promoters of this Society to see their efforts rewarded by bringing together and forming into a union so many gentlemen who practise the art of photography in Oldham, and it would be most gratifying if this change of meeting place would induce some of our townsmen who rank high in science, literature, and art, to join us in promoting the advance of an art-science that is destined to hold a very high position in the great discoveries of modern times. The other two great triumphs of genius which mark this age—the electric telegraph and the system of travelling on land and water by the aid of steam power—may be of greater commercial value (for the saving of time in steam travelling and the marvellous speed with which messages can be transmitted by telegraph are of extraordinary value), yet our beautiful art not only greatly aids our industrial and commercial pursuits, but it civilises and educates, and comes home to the affections and sympathies of the human race. It is no small boon to the humble cottager that it enables him to possess as truthful images of those he holds dear as the wealthy potentate could have done previously. What a value the poor widow places on the letter she receives from her only son, who has gone to push his fortunes in some foreign clime! But how much more precious does it become when she finds enclosed within its folds the little "carte-de-visite!" She gazes with rapture on the bit of pasteboard where stands the manly form of him who is now her only joy on earth. It is to our fascinating art that the

world is indebted for that priceless household treasure, the portrait album, on which Eliza Cook thus writes:—

"Just as the summer bee will stray  
Where rich bloom fills the woodland dells,  
Bearing the luscious drops away  
That help to store its golden cells,  
So do we gather in this book  
The great, the good, the kind, the dear,  
And bless the pages while we look  
On memory's honey gathered here."

I believe that photography, by cheaply circulating the portraits of the philanthropists and other great and good men of all nations, gives us hope that the time is coming when devastating war shall cease, and when

"Man to man the world o'er  
Shall brothers be for a' that."

I will just glance at the arts and sciences that have been benefited by photography. First, then, the science of chemistry, the parent of our beautiful art, has been repaid with bountiful interest for the nurture she gave her young protégé. The practice of photography has so popularised the chemical art as to have called into existence a new generation of chemical students. It has infused a wonderful zeal into the study of chemical science, and has caused thousands to read and study the works of our most established practical or theoretical chemists, and it is probable that even now we may be nurturing some embryo Davy or Liebig among our young and ardent photographers. The requirements of our art have called into existence several totally new combinations of matter, and wonderfully cheapened the cost of productions of some of the most useful chemicals and drugs. In medical science, the marvellous rapidity of execution and the minute fidelity of the photographic picture have been of great value in recording every varying phase and form of disease, and delineating with accuracy interesting surgical cases before and after an operation. In comparative anatomy, the minute details of the animal frame can be easily represented, and copies multiplied by the skilful photographer.

The faithful transcripts of nature produced by the camera add a new charm to the delightful studies of the botanist, the naturalist, and geologist. The geologist is indebted to our art for the accurate representations of birds and animals as yet unacclimatised in this country; and some specimens in mineralogy which crystallize in such complicated groups as to be excessively difficult of imitation have been easily copied by our art. Astronomy owes much to our art-science, and there is now a staff of photographers attached to all the observatories in the world. Warreu de la Rue has taken photographic maps of the moon, which possess such wonderful minuteness of detail that it is easy to measure the height of her mountains and the depth of her valleys; interesting photographs of the planets Jupiter, Saturn, and Mars have been taken; and lunar and solar eclipses and other remarkable phenomena have been photographed, which add greatly to the interest taken in the wonders of the celestial world. The architect must feel grateful to an art that gives him such faithful representations of existing edifices, remarkable for grandeur of conception, for beauty of execution, and for comprehensiveness of design. Views of the crumbling memorials of the genius of a past age can now be preserved by the indestructible carbon process, and future ages will bless an art that has preserved the appearance of those interesting ruins that add such a charm to our landscapes in the nineteenth century. The indefatigable photographer is ascending the Nile, tracing the course of the Zambesi, navigating the Ganges, the Yang-tse-Kiang, and the Mississippi; he climbs the Alps, the Andes, and the Himalayas; in fact, he wanders to every part of the habitable globe in search of the beautiful and the picturesque, and sends home for our inspection, at our own quiet firesides, stereographic and other views from all the principal capitals of the world. He gives us scenes memorable for past grandeur and glory; he gives us glimpses of nature unseen before, perhaps, by mortal eyes, and sends home sketches of everything that has borne the impress of human genius or skill; and, I will venture to say, that for truthfulness and minuteness of detail, they are incomparably superior to the best efforts of the painter's skill. I have said nothing of the valuable appliances of photography to civil and military engineering, to mining, surveying, and exploring; in fact, it would take a long time to show all the uses of photography, for there is scarcely a profession or business but might profitably call in its aid. I very heartily concur in the recommendation of our Council, that we hold several out-door meetings

during the year, for I cannot conceive any greater pleasure than a day's ramble with trusty camera and kindred spirits, to scenes of beauty where

"Mountain, river, lake, and grove,  
Remind man of his Maker's power and love";

where everything is clad in nature's livery, from the broad majestic oak to the tiny green blade that twinkles in the morning sun; where we are lifted for the time out of the struggles and contests of business life; where our hearts are opened to kindly genial influences, and where we feel at peace with ourselves and all the world.

These are moments calculated to awaken within us a faculty of the human mind which the ordinary pursuits of life often leave dormant: I mean the faculty of perceiving the beautiful in nature and art; a power that enables us to appreciate that beauty which everywhere surrounds us. But men wanting that faculty may live in the midst of beauty, and still not see it: to such men a stone is but a stone; such men cannot distinguish betwixt a Guido and a daub; of such a man Wordsworth says—

"The primrose by the river's brim  
A yellow primrose is to him,  
And it is nothing more."

But you, my young friends, when you have got this power—this sixth sense, as I may call it, fully developed within you—you may go forth with your cameras in search of beauty; and though she hides in a butterfly or under a leaf, or creeps into the old ivy, or plays hide-and-seek among the sunbeams, or haunts some old ruin, or laughs out of a bright young fern, or, taking the form of a white cloud, she goes dancing over the green fields or the deep blue sea, yet, by your potent art, you can transfix her, and reproduce her lineaments in her loveliest mood on the white screen. I feel proud of being a member of a society whose object is to promote the further uses and appliances of this fascinating art-science—an art that has been fostered by the highest intellects of the land. I earnestly advise our young members to avail themselves of the opportunity of studying the principles of art now so liberally provided by the excellent schools in Oldham, for unless the camera is directed by the artist's eye we can never hope to abolish these caricatures of the "human face divine" that are yet too frequently met with in albums and show-cases. I would just refer to the excellent album and portfolio that the Council have provided for the reception of gifts from members and others, and, I trust, the reading of papers, the exhibition of negatives and prints illustrating successes or failures, in wet or dry processes, and other matters interesting to the ardent photographer, will cause our meetings to be well attended, and insure the success of the Oldham Photographic Society.

[For most of the above remarks Mr. Green is indebted to several papers.]

A vote of thanks was passed to Mr. A. Whitham, of Hollingsworth Lake, Littleborough, for some very excellent cartes for the album.

It was suggested that the Society have a question-box, but the subject was postponed until the next meeting.

A vote of thanks to the President brought the meeting to a close.

## Correspondence.

### DOUBLE PRINTING.—COMBINATION NEGATIVES.

DEAR SIR,—Two years ago I gave you a plan to produce composition negatives by the use of black velvet. Again I venture to bring before you my method of producing variety in the same negative.

Select a choice bit for foreground purposes, arrange the black velvet (stretched) so as to form a background, being careful to arrange naturally all the grasses, sprigs, shrubs, &c., so that everything falls well in its place; then make a whole-plate negative, well exposed, and from the negative make a good, clear, transparent positive; place this in the window of the studio, shutting out the light all round it; then take the impression from the transparent, and immediately after take the portrait which is intended to make the picture: by this means a bit of the background from nature may be introduced without interfering with the

figure. The figure will fall in its place quite as naturally as if taken on the spot all at the same time.

This transparency will answer for any number of different portraits. The backgrounds can be introduced in the same negative by this contrivance. Go out into the woods and fields when the season comes, and take negatives from all that is likely to be useful: an endless variety can be produced in this way.—Yours very truly,

J. EASTHAM.

[Mr. Eastham's ingenious suggestion will be found in detail on page 70 of our tenth volume.—Ed.]

## Talk in the Studio.

PHOTOGRAPHY AT SOUTH KENSINGTON.—The post of Photographer to the Science and Art Department at South Kensington, vacated by the lamented death of Mr. Thurston Thompson, will, we understand, be somewhat modified. For some time past Mr. Thompson had been engaged on duties for the Department abroad, and Messrs. Cundall and Fleming had done much of the work at home. This firm will, we believe, continue doing the same duty, and the post of Photographer to the Department will be undertaken by Mr. Stephen Thompson, who, by culture and experience, is, we believe, well qualified to fulfil the duties, which will be chiefly abroad.

PIRACY OF PHOTOGRAPHIC COPYRIGHT.—On Wednesday, the 29th ult., a suit was brought before the Vice-Chancellor to obtain an injunction against the infringement of copyright in a photographic portrait. This was a suit by Mr. Mowbray, a photographer, of Oxford, against the defendants, known as Messrs. Hatchard and Co., for copying and publishing, as an engraving in a pamphlet called "The Position of the Right Rev. Samuel Wilberforce, D.D., Lord Bishop of Oxford, in reference to Ritualism," a photograph of his lordship, which, as the pamphlet stated, represented him in the attitude of a Romish bishop, with his pastoral staff in one hand and three fingers of the other lifted up in the act of blessing (as symbolical of his authority from the Blessed Trinity). It appeared that the plaintiff had taken the photograph at the request of some of the bishop's friends, and was the proprietor of the negative, which was registered at Stationers' Hall. The defendant's counsel now admitted that there was no defence to the suit, and his Honour therefore granted a perpetual injunction to restrain the defendants from publishing or selling the pamphlet with the engraving inserted, and granted an inquiry as to what damages had been sustained by the plaintiff by the publication of the engraving, and ordered the defendants to pay the costs of the suit.

## To Correspondents.

Z. H. A.—The argentometer ceases to be of value for testing a silver bath after foreign substances, such as sugar, have been added to it. If you wish to test such a solution, you must employ one of the instruments—of which there are many in the market—based upon the use of a standard solution of chloride of sodium, which, by converting all the silver in a measured quantity of the bath into chloride, enables you, by weighing the chloride, to estimate the strength of the whole solution. For practical purposes it is rarely necessary, however, to employ such a test. If you keep account of the amount of paper excited on a given solution, and take care to keep adding an ounce of nitrate of silver (and sufficient water to preserve the quantity of both) for each quire of paper floated, you will keep things in pretty good order.

NITRO-GLYCERINE.—The form of glass room of which you send diagram is very good. 2. The dimensions are very good, but five or six feet more in length would often be found useful. 3. The amount of glazing indicated in your diagram will answer well. 4. If you cannot get a north light, nor'-'nor'-west will suit well.

W. H. L.—You may safely purchase the lenses of the best English makers second-hand. The makers will willingly be at the trouble of verifying their own lenses. No. 2, in your list, we prefer.

W. J. A. G.—No. 2 will best suit your purpose for instantaneous work. 2. That marked No. 3 may be used for architecture, provided you use it for a somewhat less size than it will take; but if the straight lines of a building come near the margin of a full-sized plate, they will be curved. 3. It is impossible to describe any developer, or any formula, as best, as everything depends on the result desired, and the conditions under which you work. The best plan is to try those gelatino-iron solutions of which we have

given the formula, and adhere to that which answers your purpose best. The gelatino-iron developers generally give sufficient density at once, without further intensifying; but they may be used as intensifiers. There is no disadvantage in using an iron solution for intensifying; many of the best operators use it. Some continue to use pyro simply because they are accustomed to it, and others because they like the brown non-actinic colour it gives the negative.

G. W.—There has never been any minutely-detailed formula published of Fargier's carbon process. It was described in the *News* when first brought before the French Society in November, 1860. You will find the notice on page 390 of our fourth volume. A little pamphlet in French was published on the subject a year or two ago. The process consists in coating a plate of glass with a mixture of gelatine, colour, and bichromate, and, when dry, exposing the glass so coated under a negative. After exposure it is coated with collodion, and then plunged into warm water. This dissolves the unaltered gelatine, and leaves the image adhering to the film of collodion floating in the water. This has then to be mounted on paper. The difficulty of manipulating the soft and flimsy film, the difficulty of working with the gelatine on plates of glass, &c., stand seriously in the way of any extensive practical application of this process, and the collodion film, which covers the picture somewhat, mars the effect, especially in large pictures. We shall be glad to see your examples.

E. P. P.—Partially boiling down your bath is not of much service. To gain the full advantage of boiling, you should evaporate to dryness. Perhaps the simplest plan you can adopt is to add a few drops of a solution of cyanide to it, just sufficient to produce a slight precipitate; then sun for a few days and again try; if necessary, adding a few drops of nitric acid. A portrait lens is generally used in an enlarging apparatus. Let the focus of the condenser fall on the front lens of the portrait combination.

Z.—We have occasionally met with cases in which the collodion film has cracked under the varnish in the manner you describe. It is difficult to indicate the cause certainly, although several causes may be suggested. We fear that there is no cure. 2. It entirely depends on the kind of resin and solvent employed, as to how you should proceed to remove the varnish from a negative. If amber varnish, chloroform must be applied; if crystal varnish, benzole will answer; if a spirit varnish, then use alcohol, employing fresh quantities in succession, until the varnish is quite dissolved and washed away. The use of alcohol in subsequent solutions which may be applied to the plate will be found useful.

Z. Dobson.—It entirely depends upon whether there is any copyright in the engraving in question, as to whether you may publish photographs of it. You must ascertain that. 2. To make a bath water-tight for the field, place it in a wooden case, a little shorter than the bath. At each side of the top of the case shoulders must be placed. A strip of wood is lined with pure sheet india-rubber to cover the orifice of the bath, and this is kept in contact by a couple of brass clamps, which grasp the shoulders on the case. You will understand the matter much better by getting a sight of a water-tight bath than by a description. You will decidedly find the *YEAR-BOOK* useful.

H. WILCOX.—We should use the card lens for enlargements, stopping it well down, of course. 2. You overlook the fact that to copy and publish any man's works without permission would be very improper, especially where, as in this case, all the pictures are private portraits. 3. Systems of exchange have often been attempted; but, in all cases which have come under our attention, they have been sources of dissatisfaction. It is difficult to effect such exchange without personal examination.

W. W. LAWSON.—It is probable that, with skilful management, good results may be obtained in such a room; but it will require judgment in management. Neither the form nor the aspect are such as we should choose.

LENSES.—We think the most rapid of the two lenses will answer your purpose best in all ways.

AMATEUR.—The streaks of which you send us example are very curious indeed, and altogether unlike those which arise from over-iodizing, or those which often arise in the direction of the dip. We cannot with certainty indicate the cause. Are you sure the plates were quite clean? Had they been used for negatives before? Some imperfection of this kind is the most likely cause.

A. O. E. L.—If prints are only slightly washed, or not washed at all before toning, they tone quickly; but the toning bath is fast impoverished; no harm beyond that usually happens. If you touch the toning bath with fingers which have been in contact with hypo, the bath is quickly spoiled; a sulphur compound of gold is formed, and the bath turns brown and is inert. The only plan is to throw it into the stock of residues.

G. NICOLSON.—Frith's views are published by himself at Brightlands, Reigate, Surrey. 2. The stereo magazine used to be published by Lovell Reeves; but is, we believe, no longer issued. 3. We have not examined the book, and cannot speak certainly.

W. GALE.—One cause of your difficulty in obtaining vigorous negatives of reproductions with the materials which work well for landscapes and portraits is probably that you work with a very small

stop, and the more feeble the light which reaches your plate the more difficult it is to get clean and intense negatives. Proceed as follows:—Use a moderately strong bath with a decidedly acid reaction. Use old, full-bodied collodion, giving a creamy film, with sufficient tincture of iodine added to make it the colour of sherry. Expose in a good light and with the largest stop which will give definition. Develop with a gelatino-iron solution, not too strong; fix, and see that, before commencing to intensify, there is no deposit on the parts which should be transparent. If they are not absolutely clear, apply a solution of iodine one grain, iodide of potassium two grains, in one ounce of water, for a few seconds, wash, and apply a very dilute solution of cyanide; this will remove the traces of deposit from the transparent lines. Then, after washing, apply a five-grain solution of bichloride of mercury, until the image is of an even grey tint. Wash, and then apply a one-grain solution of iodide of potassium; this will give you an intense negative of a greenish grey tint. If it is not sufficiently intense it will now readily acquire any degree of density by the application of pyro and silver. But it is all-important to get an image with something of a positive character at the outset. The mercury intensifying process is used at Southampton. Our *YEAR-BOOK* is in print, and has been ever since Christmas week.

J. J. B.—The cost of the apparatus for enlarging by the magnesium light is, we believe, £5 12s. 6d. Mr. Solomon will, however, tell you all particulars. We shall have pleasure in giving you our opinion of your pictures.

CYMO.—It is very probable that the proposed alteration will be an improvement. From the description you give, it is not improbable that the roof, being rather low, a good deal of the light is cut off from the sitter by the sash-bars. Place yourself in the position of the sitter, and look up; if you see that each of the sash-bars cut off from your sight a portion of the sky, all that is so much practical loss of light.

G. C. M.—When once a print has begun to fade, no amount of washing will, we fear, prevent it. Placing between two pieces of blotting-paper which have been moistened with a solution of bichloride of mercury has sometimes partially restored a fading print.

ASTHETIKOS.—Failing the opportunity of securing a north light, north-east will be next best.

PIERRE REYON (Gray Haute Saone).—The two defects with which you are troubled are especially incident to the tannin process, and have never, so far as we know, been entirely overcome. For preventing the transparent insensitive spots, it has been proposed to give the plates a preliminary coating of very dilute solution of albumen; but whether this is always efficient or not we cannot say. The tendency in the latent image to become gradually effaced if the plate be kept too long before development is a peculiarity of the tannin process for which there is no remedy. 2. The addition of honey, or similar substances to the honey, only tends, we believe, to hasten the disappearance of the image. 3. The collodio-albumen process, with a final wash into a solution of gallic acid, is the best keeping process we know. The modified gum process described in our *YEAR-BOOK* by Mr. Gordon is an excellent keeping process. 4. With some samples of collodion, when using the last-mentioned process, the film has a little tendency to leave the plate, but with an adherent collodion this is not so.

H. P. (Thirsk).—Thanks: we shall be glad if we can find time to avail ourselves of the opportunity of seeing the pictures.

W. FISHER.—As we read and answer considerably over two thousand letters from correspondents every year, you can readily conceive that we do not preserve in our memory every individual design for a studio submitted to us; so that, without receiving another copy, we cannot now advise you concerning one sent some time ago. We can advise you generally, however, that it will be wise to get your light from the side which has an uninterrupted expanse of light.

TOP-LIGHT.—We have an impression that in summer blinds are occasionally used to the top-light; but we described it as it was used in October. Stippled glass obstructs considerable light, and blinds would rarely be required as well. 2. In intensifying with the same iron solution as that used for developing, it is clear that a considerable amount of acid must have been present to check reduction. 3. For blinds to your roof we prefer the scheme marked No. 1, with the blinds half covering the glass, running in the direction of the dotted line D and E. We should not cut off any of the side-light. Thanks.

S. ARLIDGE.—Your background is not bad for a first attempt; but it is a little too much pronounced. A larger style of painting, with fewer objects in the scene, many of them being rather indicated than sharply made out, is most suitable for photographic backgrounds. We shall have pleasure in hearing of the results of your experiment in lens making.

Several Articles again stand over.

Several Correspondents in our next.

\* \* All photographs forwarded to the Publisher for registration receive attention at once; but the pressure on our space sometimes compels us to defer the acknowledgment in this column. It should be borne in mind, therefore, that non-acknowledgment at once does not necessarily imply non-receipt or non-registration.

## CHANGES IN PHOTOGRAPHIC GLASS.

THE extent to which photographers habitually waste light is a question worthy of more careful and more general study than it has ever yet received. Every photographer knows that quality of light is more important than quantity; that no length of exposure will ever fully compensate for lack of purity or brilliancy in the light; and portraitist and landscape photographer alike avoid working, if possible, in foggy weather. Yet it is a literal fact that many photographers are voluntarily working in an artificial fog, or its equivalent. Many are continually working in studios with an accretion of dirt on the glass which renders it as impervious to light as ground glass; and many more are working with glass which, whilst kept clean, has undergone a gradual change under the action of sunlight which has made it retard the passage of actinic rays in an almost incredible degree.

At the last meeting of the North London Photographic Society we brought this subject before the members, chiefly confining ourselves to the condensation of the record of a series of interesting experiments by Mr. Gaffield, of Boston, U.S., with a copy of which he had favoured us. We then briefly referred to cases which had come under our own knowledge, in which a thorough cleaning of the glass of the studio had reduced the exposure one-half. Since then the details of a case were brought under our attention in which the change effected was much more startling. An eminent photographer was asked to inspect a glass room which appeared admirably built and arranged, and in which excellent pictures were obtained, but which, from the length of exposure required in it, rendered the studio comparatively useless. A careful inspection of the glass induced him to ask for hot water and flannel, and a transparent, brown film or varnish, the accretion of many years, was removed. After a perfect cleansing within and without, a picture was again tried, and it was found that the exposure had been reduced from sixty seconds to ten seconds. And yet the accumulation of deposit on the glass had been so gradual, and it was so much of the character of a thin, tenacious, but non-actinic film, that it had never excited suspicion until examined by a gentleman to whom it had not grown familiar. A similar case was brought under our attention in relation to an excellent quarter-plate—Voightlander's portrait lens—once excellent, but which had grown so slow as to be worthless, an absolute change in the colour in the glass being suspected. The lens had so deteriorated that it was offered for sale for five shillings. A friend suggested to the owner examining the surface of the glasses, and received reply that they had been continually carefully wiped and polished. It was resolved, however, to give them a thorough cleansing with a tuft of cotton-wool dipped in alcohol. This at once revealed the presence of a yellow film, which had before resisted cold water and gentle wiping. Each lens of the combination being thoroughly

cleansed, the lens recovered its original rapidity, and became worth as many pounds as it had been offered for shillings. Every one who has given attention to the subject must be aware that the film which gradually deposits on surfaces of glass is often very tenacious, insoluble in water, and not easily removed by ordinary rubbing. The use of alcohol, dilute sulphuric acid, or (what is too little known) a strong solution of sulphate of magnesia, will generally be found efficient either for lenses or other glasses.

The effect of colour in glass, and the changes made by the action of light, receive, perhaps, less attention than those made by dirt; but they are less understood and less under the control of the photographer. Mr. Gaffield has very definitely proved a fact to which we have before called attention, namely, that the most colourless glasses are most liable to injurious change; and he has further ascertained that almost all kinds of glass are liable to change under the long-continued action of sunlight, twelve months sufficing to alter the colour of every sample exposed except a common sample of American sheet glass. Fortunately for the builders of photographic studios, the commonest glass, as a rule, is least liable to change, English crown bearing—in this country at least—the best character in this respect. But it unfortunately happens that some samples of this glass, of one-eighth of an inch thick, cut off as much as 13 per cent. of light. M. Pelouze has stated his belief, in the *Comptes Rendus*, that there is not a single species of glass to be found in commerce which does not change under the action of light. But Mr. Gaffield has found that a sample of optical glass did not change in two years.

There are three practical questions arise out of a consideration of the subject. First—Can glass be made which shall not change? The second is a compound question—What kind of existing glass, not obstructing much light, changes least, and which most? And, thirdly—What kind of changes are least injurious photographically?

In answer to the first, Mr. Gaffield states that if manufacturers would make glass of materials free from impurity, a glass free from risk of change might be produced. The common impurity is oxide of iron, which, in the form of a protosalt, causes greenness in glass, and in the form of a persalt causes yellowness or brownness. To correct the green tint caused by iron, oxide of manganese, or "glass-makers' soap," is added. A portion of the oxygen combining with the iron salt changes the green into yellow, and, thus corrected by the pink tint of the manganese, gives a comparatively colourless effect. The balance upon which a colourless condition is based being easily affected by light, the changes to yellow or pink are produced. The only stable freedom from colour must be gained, it seems, by the use of pure materials and a careful abstinence from the addition of manganese. Will glass manufacturers make the experiment in behalf of photographers?

In answer to the second question, the existing samples of white plate change most readily, becoming yellow; and next to this, white Belgian sheet, which quickly changes to pink. The least easily changed are common sheet and crown glass, either English or Belgian. Samples of a bluish green tint obstruct least light when new, and are least liable to injurious change.

The kind of change least injurious in glass for photographic purposes is obviously that inclining to lavender or purple, that tending to yellow being most injurious. We recently tested two samples of thick plate glass, such as is used in printing frames. Both had been colourless; one had acquired a slight yellow tint, but still looked clear and brilliant; the other appeared much darker and inclined to purple. A piece of sensitive paper being exposed under them for five minutes, strikingly illustrated the resistance to actinic light. That with the purple tint obstructed very little light. Estimating the uninterrupted action of light on the paper as 7, that under the purple tint would be 6, and that under the yellow tint about 4. Photographers contemplating glazing studios cannot, unfortunately, make practical tests with advantage, as few would care to wait six months—the shortest exposure giving any trustworthy indications of the character of any glass to be examined. Until a guaranteed sample is in the market, relying on the indications we have given, and occasional examination of the glass, and, if necessary, reglazing, are the only resources he possesses.

No available means have been discovered of restoring the purity of glass changed by light. Some time ago Dr. Percy called our attention to the action of heat in removing the pink colour produced by light, and Pelouze has made similar observations; but baking the glass in the studio is not readily effected. It is easier to break a few, at least, of the panes through which the dominant light enters, and renew them by the lightest sample of bluish green window glass to be procured.

#### THE LATE SIR DAVID BREWSTER.

ANOTHER of the foremost men of science of our day, and an able contributor to the scientific advancement of photography, has left us. Sir David Brewster has died in his eighty-seventh year, having been born in December in 1781. His life has been for nearly seventy years actively engaged in the pursuit and promotion of science, his labours being recognized in his twentieth year by an honorary degree as M.A. conferred by the Edinburgh University. Scholastic honours from various sources followed, and in 1831 he was made a Knight of Hanover, and in the following year received an English knighthood. His labours have been devoted to many branches of science, but the science of light has secured his chief attention. His works on optics, on the polarization of light, and other branches of the science of the sunbeam, are well known. One of the most valuable labours of his life was the effort made in forming the British Association for the Advancement of Science, of which he was the virtual founder. His practical inventions were not less interesting than his contributions to abstract science. Of the indirect aid which his labours have lent to photography it would be difficult to speak with precision, they are variously ramified; but his contributions to the perfection of lenses, and his invention of the lenticular stereoscope, are well known. He preserved at all times a deep interest in photography, and in the Photographic Society of Scotland, of which he was President. He contributed to photographic literature various interesting articles in the *North British Review*, and elsewhere. He manifested a deep interest in the recent discussions on the improvement of photographic lenses, in which the late Mr. Claudet and others were engaged, and maintained with that gentleman an animated correspondence on the subject, with a sight of which Mr. Claudet from time to time favoured us. In a recent letter, he enclosed to Mr.

Claudet a small photograph of a very humble cottage in Jedburgh, with an inscription intimating that it was the house in which he was born upwards of eighty years ago. Although Sir David had been seriously ill for a little time before he died, he had retained the vigour of his faculties to the last, having continued his scientific labours until within a very short period of his death.

#### DESCRIPTION OF AN IMPROVED FRAME FOR PHOTOGRAPHIC PRINTING.

BY ARTHUR TAYLOR.

COMPLAINTS have frequently arisen as to the inefficacy of the pressure frames used for photographic printing in procuring that equable contact between the whole surface of the negative and the sensitive paper which is essential to the production of good prints.

There is, no doubt, much ground for these complaints, especially where large frames are used in hot climates; and the defect seems to arise from the fact that, in the frames commonly used, the pressure is applied at one or two points only of the boards forming the back of the frame; so that, to effect an equable pressure at all points of its under surface, the backboard must be a true plane, and, moreover, perfectly rigid.

Backs of plate glass have been used in some cases, but they are hardly applicable to large frames; for although they certainly fulfil the first of the above conditions, they are open to objection on the score of weight and fragility, and unless very thick, they are not sufficiently rigid; whilst, on the other hand, those made of wood, in the usual way, are very apt to warp, and an exceedingly slight deformation in this part is fatal to the proper action of the press.

The annexed drawing represents a form of printing-frame

in which the above-mentioned causes of imperfect action are avoided. Several frames on this plan, of a size 14 inches by 11 inches, have been in use for the last six years, and although the printing has usually been done in the hot sun of the south of France, they are still in perfect working order.

As the drawing is made to scale, it gives the relative proportions of the parts, suitable for forms of various sizes; but the following description is that of one of the above-mentioned frames, measuring about 14 inches by 11 inches in the clear.

The frame itself is box-shaped, the sides being about seven-eighths of an inch thick,  $1\frac{1}{2}$  inch deep from back to front, and carefully dovetailed together. The front part of this frame having been worked thoroughly out of winding, slips of wood are screwed on, which form the rebate, to receive a plate glass about three-sixteenths of an inch thick. In some instances, sheet caoutchouc has been placed between the frame and the slips forming the rebate, so as to make an elastic and water-tight bearing for the glass.

The back is divided into two equal parts, which may be opened separately. These backboards are of flexible wood, one-quarter inch or five-sixteenths of an inch thick, with the grain in the direction shown in the drawing, and no attempt must be made to stiffen these boards by framing the ends, or otherwise, for it is essential that they should bend freely. On each backboard are placed two pieces, having the form of right-angled triangles; they are of one-quarter inch board, and are attached to the backboard by a wood screw at each corner, but each screw passes through a small washer of sole-leather, placed between the backboard and the triangle. These discs of leather form the bearing-points of the triangles, and they are distributed in such a manner that each occupies the centre of an equal area of the backboard.

A curved steel spring, about one-sixteenth of an inch thick and one inch wide, rests its ends on two points situated in the adjacent triangles; these points being the centres of gravity of the triangular surfaces. The ends of the spring are curved up, and are attached to the wood by screws passing through oblong holes in the spring in such a way as to allow a certain amount of play.

Finally, over each spring is placed a cross bar, two inches wide by half an inch thick; this cross bar is hinged on one side of the frame, and may be secured on the other side by a hook and staple. A short, but rather thick, round-headed wood screw is set in the under side of the cross-bar in such a way that the hemispherical head may rest in the centre of the spring beneath.

Now, when the cross bar is pressed down, the pressure is transmitted to the spring, and is divided between its two extremities, which press with equal force on the two triangles; these two secondary pressures, again, being applied to the centres of gravity of the triangles, are decomposed into six perfectly equal pressures, acting on the backboard through the bearing-points; these last being, as before explained, equally distributed over the area of the backboard, it follows that the pressure originally applied to the crossbar is disseminated in a very equable manner over the whole area of that part of the back which it is intended to compress. A piece of thick woollen blanket, placed under the back, still further equalizes the pressure, and transmits it to the sensitive paper. Between the blanket and the backboards should be placed a piece of thick paper or of card.

The backboards are, of course, liable to warp, but this is of no practical importance, for being, as before stated, thin and pliant, they yield to very slight pressure on the crossbar, and mould themselves, as it were, to the form of the surface beneath. If thought necessary for any special purpose, this last action may be still further facilitated by sawing the backboards nearly through from the back, and midway between the bearing-points, thus dividing the boards into a series of equal and nearly independent parallelograms, each with a bearing-point in the centre.

The amount of pressure is easily regulated by means of the screws in the crossbars, and, once set to suit any given negative, remains constant, however often the frame may be opened.

The crossbars are made of hard, elastic wood, such as ash, and their hinges of thin sole-leather. Metallic hinges are objectionable, for unless they are oiled they wear rapidly, and the fine metallic dust from them may occasion spots on the prints during the process of fixing. It has not been found necessary to hinge the backboards together, though, of course, it may be done if thought desirable.

It may be mentioned that the frames above described have, as yet, been used almost exclusively for printing from paper negatives, the positive paper employed being very thick and hard drawing-paper, frequently requiring a very heavy pressure to flatten it; the pressure distributed over the whole area of the front glass has commonly been one hundred and twenty pounds or more, yet none of these glasses have ever given way, as would, no doubt, have been the case had such a pressure been at all localized. Of course this amount of pressure is only required for special purposes, and the construction of the frame admits of its being moderated to any extent to suit the fragility of glass negatives.

It must be particularly remarked that, when printing from glass negatives, it is essential that the plate should be nearly the whole size which the frame is made for, as it will at once be seen that a small plate placed in a large frame would receive a very irregular pressure. This, however, can hardly be considered as an imperfection peculiar to the frame proposed, for none of those in common use is free from it.

The same principle can be employed in the construction of frames much larger than that described; and if, for very large sizes, a greater number of bearing-points is desired, they can always be so connected by triangles and levers as to divide the pressure of the crossbars equally amongst them.

When it is not necessary to examine the print during exposure—as, for instance, in carbon printing—the frame might be made with a single crossbar; and if, on the other hand, it is desirable to uncover more than half the print to facilitate its examination, three or more sections of backboard, with corresponding crossbars, may be used. It may be observed, in conclusion, that these frames, being very easily made, should not be costly.

*Marsilles, January, 1868.*

#### GLASS FOR PHOTOGRAPHIC PURPOSES: AND THE CHANGES OF COLOUR TO WHICH IT IS SUBJECT.

BY G. WHARTON SIMPSON.\*

It is not a little remarkable that a substance like glass, entering so largely into the consumption of the photographer, and so materially affecting his operations in a variety of ways, has received so comparatively little attention, is so comparatively little understood, and remains so much beyond his control. Photographers will study with anxious concern to secure a collodion which shall give them an increase of sensitiveness amounting to 10 per cent., and would consider a developer which reduced their exposures by 15 per cent. a boon beyond compare; and yet it will often be found that they are shutting out light from their studios amounting to 25 or even 50 per cent., without the slightest feeling of concern. Even in the matter of dirt accumulated on a skylight, I have often been astonished to see it allowed to collect year after year, obstructing light to a most serious extent. And I have known cases where, after a thorough cleaning of all the windows in a studio, the exposures have been reduced one-half.

General experience has taught, what special experiment

\* Read before the North London Photographic Society, February 5th, 1868.

has confirmed, namely, that almost all kinds of glass change under the action of sunlight. Different kinds of glass change in different degrees, and the change which takes place varies in kind as well as in degree; some samples tending towards yellow in their change, and some towards pink or purple. The former change is of by far the greatest importance to the photographer, inasmuch as it has been ascertained that a very slight tinge of yellow will cut off 25 per cent. of the actinic rays, whilst the change towards the purple, although of course it cuts off some light, transmits, as we should expect, the actinic rays much more freely, as I shall presently illustrate.

As this question is of vital importance, not merely in regard to the glass employed in our studio, but also in regard to the glass employed for negatives, which are often noticed to print slower after long exposure, the subject is, I think, well worthy of a much more careful attention from photographers than it has hitherto received.

My duty will be chiefly confined to bringing before you the most important points in an interesting paper on the "Action of Sunlight on Glass," recently contributed by Mr. Thomas Gaffield to the *American Journal of Arts and Sciences*, in which he describes a most exhaustive series of experiments. These have been conducted during four years with about sixty varieties of glass, the results having been carefully tabulated. In some cases the records contain the changes observed from day to day, in others from month to month, and others from season to season. The glasses examined consisted of one specimen of optical class; a few kinds of flint glass and glass ware; sixteen kinds of French, Belgian, German, and English plate glass; four kinds of American, English, French, and Belgian rough plate; two of American and English crown glass; ten kinds of American, Belgian, French, and English white sheet glass; four kinds of American, Belgian, and English ordinary sheet glass; fifteen kinds and shades of English coloured glass, four of opaque, white enamelled and ground glass, and one piece of the rough metal of American sheet glass.

It will be noted that Mr. Gaffield's experiments not only confirm what was known in this direction, but materially extend the domain of our knowledge; and further experiments, to be extended over ten or more years, will, there can be no doubt, throw still more light on the subject. In the meantime, his experiments commenced in 1863, and, continued since, are very interesting; and the extracts or abstracts I shall make from his paper will, I believe, be found of much value to photographers.

The first experiments, in July, 1863, proved that,— "a month's exposure to a hot sun would change the best white French plate and all white sheet glass, such as is used for photographs and engravings, to a colour containing more or less of a yellow hue. The dark green and dark blue or bluish green did not experience any change; but any hue which approached a white, whether bluish, greenish, or yellowish white, turned to a yellowish colour.

"A second series of experiments, commenced in July, and continued three months, on some thirty specimens from France, England, Belgium, Germany, and the United States, only confirmed the results of the first; and a daily examination at first, and afterward from week to week, and month to month, revealed the interesting fact that, even after a single day's exposure to a July sun, the change of colour would, in some instances of the lightest hues, commence."

Further experiments in the same direction were tried, with similar results; the samples of glass employed being, in each case, "what is called colourless window-glasses, although they varied in tinge and hue from the whitest improvement to the darkest green English sheet-glass. An Mr. Claudet and four months, from July to November, on that gentleman an <sup>23</sup>—red, green, yellow, blue, and purple object, with a sight of <sup>24</sup>—in the purple, which became time favoured us. In a recent

changed thus seriously, he "noticed that the dark green, blue, and bluish-green did not change. The colour of the Belgian sheet (called German or French by glassdealers in America), a yellowish or brownish-green, did not change; and these were the only exceptions. All plate-glasses changed, except an inferior blue quality, and a superior crystal plate of a greenish colour, made in Germany, and at the only factory which has not given up the use of potash for soda-ash."

During the first course of experiments he found that many examples of sheet, plate, and crown glass, with various tints of green, bluish green, and yellowish green, which remained unchanged during an exposure of three months, in twelve months, underwent similar changes to the colourless glass, one sample only—an ordinary American sheet of a bluish green tint—remaining unchanged after a year's exposure.

The gradual nature of the change, and the different tints obtained, in some samples are interesting, "commencing in a day or a few days in summer, from greenish or bluish white to a yellowish white, or light yellow, a deep and deeper yellow, until it becomes a dark yellow or a gold colour; and in some Belgian sheet specimens, a gradual change, commencing in a few weeks in summer, from brownish yellow to deeper yellow, yellowish pink, pink, dark pink, purple, and deep purple; and some kinds of greenish white glass would, after exposure, assume a bluish tint or bluish white."

The following memorandum of the changes during a year's experiments presents the results in a clear form, useful for reference:—

*Memorandum of Nine Different Kinds of Glass exposed from Jan. 12, 1866, to Jan. 12, 1867.*

Kind of Glass.	Colour before Exposure.	Colour after Exposure.
French white plate	Bluish white	Yellowish colour
German crystal plate	Light green	Bluish tinge
English plate	" "	Yellowish green
English crown	" "	Light purplish colour
Belgian sheet	Brownish yellow	Deep " "
English sheet	Dark green	Brownish "green "
American crystal sheet	Light bluish white	Purplish white
" " "	Lighter bluish white	Light yellowish green
" ordinary "	Bluish green	No change

"The colours named above are given from an observation of the glass edgewise, by which one can see a body of colour two or four inches in depth, whereas the usual thickness of the glass varies from one-fourteenth to one-quarter of an inch, and shows its colour easily only by placing a white curtain or paper behind it."

An incidental observation is interesting, as illustrating the comparative actinic power of the sun's rays during different months. Mr. Gaffield says:—

"I have tried several experiments showing the effect of sunlight during each month and each season of the year. At the end of the year, by the comparative depth of yellow or purple colour produced in the various specimens, one can see the comparative actinic power of the rays during each month and season. The results proved that the actinic effect increased from January to July, and decreased after that month. The greatest effect during any season was observed in the summer, the least in winter, and that in spring and autumn was about alike, and midway between that of summer and winter."

Some other incidental observations as to the power of various glasses to transmit the actinic rays should not be omitted here. Mr. Gaffield remarks:—

"The comparative power of glass of different kinds to transmit the actinic rays, I have tested by placing underneath pieces of each kind, pieces of easily-changing glass (white plate or Belgian sheet glass), exposing them one year, and noticing, at the end of that period, the comparative depth of the yellow or pink colour to which the under pieces had changed. The result of my experiments proved that the most easily transmissive of the colourless glasses were the English crown, French plate, two kinds of white

crystal sheet made in Massachusetts from the celebrated Berkshire white sand, the new Jersey sheet glass, one kind of English plate, and one kind of Belgian sheet, and about in the order which I have named them.

"Of the coloured glasses, the blue transmitted the most, the purple less, the red and orange the least, the glasses under these two and the yellow and green showing little or no change.

"This last experiment proves the propriety of the preference given by photographers to blue glass for skylights, because it transmits the blue rays, which exert the most actinic power. But it may be added that a colourless white glass, or bluish white—if one which will not change by sunlight to a yellow or rose colour, owing to the presence of manganese, or any other cause—is equally good, as it will transmit all the rays, and among them the actinic or blue ones. In proportion as any kind changes to a yellow or rose colour, it will lose its power of transmission and its value as photographic glass. I have seen specimens of the two kinds of white crystal sheet made in Massachusetts before alluded to, which answered the demands of photographic artists. Of foreign glass, I have noticed a fine bluish white sheet, made lately without manganese, from a certain excellent manufactory in Belgium, and one kind of English crown glass.

"Should plate glass be required, the most permanently enduring, or least likely to assume a yellow colour, are a superior kind of white plate, made by the French and Belgian Plate Glass Companies, and an excellent quality of German crystal plate, made at a long-established factory in Hanover.

"I desire to say here, however, that it is not the place where any glass is made which determines its good character, but the actual constituent materials and the superiority of its manufacture.

"Manufacturers are frequently changing their mixture or 'batch,' so that any results given with one set of samples might differ from those made with another set from the same manufacturers. For this reason, in noticing any differences which may occur in experiments made by any of our readers, this fact should be considered as an explaining cause."

After stating some experiments for the purpose of proving that it is to actinism alone, and not to heat, moisture, &c., the change is due, Mr. Gaffield proceeds to state his view of the cause of the changes, which are due to the metallic oxides present. He says:—

"We will briefly state the part which the oxides of iron and manganese play in glass making. In almost all kinds of window glass, and in some poorer qualities of flint glass and glass ware, materials are used which are not perfectly and chemically pure. The sand, the carbonate or sulphate of soda, and the lime, one or all, contain slight impurities of iron, the protoxide of which gives glass a green colour. To correct this, after the batch is partially melted, a little oxide of manganese, called *glass-maker's soap*, is put into the crucible or glass pot; some of the oxygen of the manganese flies off to the iron, and converts the protoxide into peroxide of iron. The peroxide gives a yellowish colour to the glass, and this, being complimentary to the natural pink of the manganese, is neutralized, and the glass is thereby made of a light colour. When the sunlight acts upon glass thus made, the nice equilibrium between the oxygen of the iron and the manganese is disturbed, and sometimes the yellow, and sometimes the pink or purple colour is produced. I have produced all shades of the purples, running from pale lavender into the lilac, mulberry, flesh, amethyst, rose, violet, pink, and deep purple. I have produced, or seen specimens, showing all shades of the yellow, from the brownish yellow up to the brightest gold colour, and I have several series of specimens in which the green has gradually changed into the yellow, and the yellow gradually ran into the pink and purple."

The most important photographic application of Mr.

Gaffield's experiments will be found in the following paragraph:—

"My experiments with glasses under other glasses proved which was best for photographers' use, information which all can gain by exposure of the specimens of various manufacturers which may be offered them. The most pure glasses of light green, or bluish white colour, are the best for photographers, and when I say *pure* glasses, I mean those most free from oxide of iron or manganese, but especially of the latter, which, I think, is the cause of nearly all the changes which I have observed."

Before concluding, I should remark that Mr. Gaffield's articles in the *American Journal of Science and Art* contain full details of the careful mode of testing and examination adopted, from which we may conclude that his results, so far as they have gone, are precise and trustworthy, having nothing of the nature of conjecture or guesswork in the mode of conducting them. The subject is, I think, one of most vital importance to photographers, and one well worthy of a very thorough investigation.

## PICTORIAL EFFECT IN PHOTOGRAPHY;

BEING LESSONS IN

COMPOSITION AND CHIAROSCURA FOR PHOTOGRAPHERS.

BY H. P. ROBINSON.

CHAPTER 3.

"Thus we are agreed:

I crave our composition may be written."—*Shakespeare.*

"Form is matter bounded by lines, which may be either angular or curved."—*Sir Thomas Dick Lauder.*

"The accidental compositions of heterogeneous modes are dissolved by the chance which combined them; but the uniform simplicity of primitive qualities neither admits increase nor suffers decay."—*Dr. Johnson.*

Composition in art may be said to consist of the selection, arrangement, and combination in a picture of the objects to be delineated, so as produce an agreeable presentation of forms and tones, tell the story which is to be elucidated, and to embody the spirit of what it is intended the picture shall represent or suggest. The principal objects to be sought are harmony and unity. By the preservation of a harmonious balance of lines and light and shade several objects are attained. The first and simplest result is the production of pictorial effect, which satisfies the eye without reference to the meaning or intention of the picture. But a higher purpose is also served. The preservation of harmony necessarily involves the idea of subordination, or a consideration of the relative importance of all the parts of the picture, the principal objects being made prominent, and the minor objects made auxiliary to that prominence by the arrangement of lines and masses of light and shade. By a proper distribution and balance of these the principal objects in the picture will be brought prominently forward, and those of less consequence will retire from the eye, and will support or act as a foil to the chief objects of interest. As the quaint old writer on art, Lairese, recommends, "Let the king or prince have the first place, and next his retinue or other proper persons; if there be yet another party to be introduced of lesser moment than these, and yet essential to the composition, put them in the shade without more ado." In short, the grand fundamental laws of composition may be summed up very briefly. They are, unity, balance, and the adaptability of the whole to breadth of light and shade, by which the principal object in a picture—such, for instance, as the head in a portrait—is brought forward most prominently, yet united with the other parts, so that the eye may first see the point of chief interest, and be gradually led over the other parts of the picture. In addition to the above primary necessities in composition, there are many subdivisions belonging to harmony—such as repose, subordination, repetition, variety, &c.—which will be treated of in their place, after the broad principles have been clearly understood.

It is a curious fact that the pictures by all artists that have lived during the last three centuries—or, at least, all those

pictures that have come down to us—appear to have been designed on some fixed principle; and from a consideration of the best works of the great masters it has been found that all the most pleasing and agreeable compositions are formed, more or less, on the leading idea of the triangle or pyramid, the diagonal line and its contrasts (which is a variation of the same thing), and the circle, with its various modifications. From a study of these facts, Burnett and other writers on the subject have divided the art of composition into angular and circular, whilst many of the finest examples are a combination of both forms.

As being of the first importance, and constituting, in fact, the skeleton on which all other parts of this subject hangs, it will be well to first call the student's attention to a consideration of

#### THE BALANCE OF LINES.

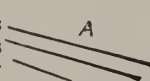

All lines should be balanced or compensated. Without a due regard to this important quality a picture would appear ready to fall to pieces.

Example: Lines running in one direction, whether parallel or otherwise, would give a weak and awkward appearance. A sense of falling is conveyed to the mind by

lines repeating each other thus  It will always

be found possible to produce compensating lines in other parts

of the picture thus  or if lines run diagonally

down a picture thus  a compensation for the lines A is B. There are many other ways in

which oblique lines may be compensated, in a great measure depending on the ingenuity and skill of the artist. Here is an example in a portrait (fig. 1): A girl

Fig. 1.

chair would topple over, which would not have a pleasant effect on the beholder. But to counteract this sense of danger, the lines A, B, and C have been balanced by the line of the drapery D; and this not being sufficient, the table E has been introduced, while the dark spot caused by the book also helps to support the composition, as will be further explained in this chapter. This example is taken from an actual photograph, and shows, as I hope to show by other sketches also taken from photographs, how it is possible for the photographer to apply these rules to his art.

Sometimes the repetition of lines without balance is useful. A good illustration of this is to be found in Frost's pictures of Sabrina and her attendant nymphs descending to the halls of Nereus, engraved and published by the Art Union some years ago, and already familiar, or readily accessible, to all my readers. In this picture all balance of lines and equilibrium of base have been purposely omitted, and the figures appear to descend through the water—an effect necessary to the story.

It may be said that as diagonal or pyramidal lines require compensating, why use them? Why not use the horizontal and vertical lines? To which it may be answered, that there

is not sufficient variety in the last-mentioned lines; a square is much less picturesque than a pyramidal form, as may be seen by comparison of a modern house of square elevation with a Gothic church and spire. Besides, nature never composes in squares; even the horizontal line of the sea is broken by the lines of the clouds and the waves, and that of the plain by trees, uplands, and mountains. Again, a row of standing figures all of the same height, although it is often to be found in photographs, is eminently monotonous and disagreeable; and the very fact that groups of figures are so often photographed in this manner shows the necessity for this work.

The diagonal line (fig. 2) is very suitable in the composition of landscape; it lends itself so admirably to the receding lines of perspective.

Fig. 2.

Nearly allied to balance of lines is

#### CONTRAST.

Which is the opposing of things of different aspect to each other, so as to bring out the fullest and best effect of each; such as the position and variety of heads, youth and age, light and shade, &c. Indeed, contrast sometimes supplies the place of balance, as in the sketch (fig. 3), which shows the leading features of a photograph by Mr. Blanchard, whose marine views are always well composed, showing the power of the photographer over subjects consisting chiefly of sea and sky, where the darkest spot—the boat—is opposed to the highest light, and, being the nearest object, is opposed to the most distant, thus giving effect to each other, and being also at the base of the angle, supports the whole, and acts as a kind of key-note to the entire frame-work of the composition. This form of composition, with the endless

Fig. 3.

variations of which it is capable, is most valuable to the landscape photographer.

In concluding this chapter, I must remind the student that in following up the above hints in his pictures he must not allow the art to become too evident, the effect of which would be painful. Just as the conversation of a very learned person is sometimes dull, so would his work be if the student

made too great an effort to show his knowledge. He must not leave room for the critic to say—

"Nature in him was almost lost in art."

The axiom that those who use most art betray the least, is, to a certain extent, true enough; but too great an effort to conceal the art might lead to weakness, and destroy simplicity and character. That which hits the happy medium will be the greatest success.

## THE MAGIC LANTERN AND PHOTOGRAPHY.

BY JAMES MARTIN.

No. 6.

As before observed, the directions and explanations given are not supposed to apply to any particular design, but to explain generally the method of transparent painting upon glass. My readers, remembering that the difficulty of describing a process of colouring without having a coloured illustration to refer to is very great, will pardon me if in part I should appear obscure; in such case do not hesitate to apply to me, and I shall have much pleasure in adding the necessary information through this Journal. Having adjusted your easel at such an height and inclination as may be most convenient for working upon, and in such a position as to be opposite the light, which must be thrown upon the white paper placed underneath, and reflected through the outlined glass or photograph to be painted, which is now separated from the copy and laid upon the easel, he will begin, as in painting generally, with the sky and distances. But I must first state, that in addition to the appliances already named, you must also be provided with what artists term a dipper, which is a small tin cup, whose bottom forms a clip, which fastens it on some convenient part of the palette, and out of which the painter takes the vehicle to moisten his colours from time to time with the tip of his brush. An egg-cup will serve the purpose very well if not required to be fixed on the palette, which is not absolutely necessary for such small work as glass painting. The vehicle generally used is mastic varnish, thinned with turpentine; in cases where the colours to be used are bad driers, a little japanners' gold size may be added, or a French preparation called *siccatis*: by these means, and avoiding the use of oil, the painter may work on without needing to wait for intervals of drying. Take a moderate-sized camel's-hair brush, and, with a little of the vehicle, make a tint of madder lake and Prussian blue; beginning at the top of the picture, lay the colour from left to right evenly all over the sky, so that a pearly grey tint may be produced, gradually melting away at the horizon to almost clear glass; then, with the dabber or the tip of the finger, soften the colour evenly all over, so that it has the appearance of a minute and extremely fine stipple. The darker clouds are formed of Prussian blue, madder lake, and a little gamboge. Be careful to observe their forms and character, leaving their half-lights, which will be retouched with some of the same tint, but somewhat lighter, and having a little more gamboge added. The edges and oppositions of the sky may appear hard; in that case, the application of the finger or dabber will be necessary to soften and blend them; but it must be carefully done, and not overwrought, or the tints will be vitiated. The dangers to be apprehended from a too free use of the dabber are the same as those to which the artist is liable from an excessive use of the softener; the roundness and substance of the forms are lost, and the colours are muddled. It is sometimes useful to have smaller dabbers than can be made of leather; for such, camel's-hair pencils, with their points cut square and then slightly singed round their edges in the flame of a candle, answer the purpose well.

We will now proceed with the mountainous distance. Those forming the horizon or distance are nearly the same tint as the sky, and are devoid of detail, therefore will be represented by a flat tint; but as they approach the middle

distance, the colour increases in intensity until they correspond in tone with the darker parts of the clouds, and a slight marking of details begins to appear. Lay evenly over the tops of the mountains a tint made of madder lake and a small portion of Prussian blue, adding more blue as they approach the middle distance. The lights must be painted with madder lake and gamboge, broken to a warm grey with blue, then blend the whole with a small dabber, taking care to preserve the outlines; the middle distance is composed of the mountains behind the castle, the rocks and green slopes edged with trees, and will prove the most difficult part of the picture from the situation of the light; the mountain behind the castle will be a mass of light and half-light; the second, of shade and half-shade; the third, and nearest, shade and half-shade in a greater degree. Paint in the forms at the tops of the mountains with gamboge, madder lake, and Prussian blue. Continue half way down, then add more lake by degrees, and with this all the dark parts may be laid in, even where most positive in colour. The lights in the tops of the mountain are made of gamboge and madder lake; the light at the base and on the slopes are a greyish green, made by adding a small portion of blue; the dark parts of the rocks are made out with a tint of madder brown and Prussian blue, the lighter parts with gamboge and brown madder. Vandyke brown and blue are used for the darkest markings: the foliage must be laid in with gamboge and madder lake. The bright points of light glancing on the trees are tinted with gamboge only. The dabber must be used to soften every part that requires it, and lights that are troublesome to have can be taken out with the point of the penknife, and afterward retouched with the required tint; and in laying flat tints it will be more expeditious to work over any foreground objects, and afterwards remove the superfluous colour with the stump or a camel-hair pencil containing a little turpentine.

114, High Street, Ilfracombe, Devon.

## ON A WET METHOD OF REDUCING CHLORIDE OF SILVER.

BY DR. GRAEGER.\*

THERE are many methods of reducing chloride of silver with which we are acquainted, but the majority of them are surrounded by difficulties of some kind or another; either the silver recovered is not perfectly pure, or the manipulation of the process is attended with serious loss, or it is impossible for the whole of the chloride to be reduced at one operation. Now as the reduction of chloride of silver is an operation which has very frequently to be performed, a method whereby these difficulties are overcome will be welcomed with pleasure; and so often have I felt the shortcomings of the methods at present employed, that it has always been my constant endeavour to discover a better and more serviceable mode of proceeding. In making my enquiries, I have always had in view the advisability of seeking for a wet method of reduction, as I regarded the same as the easiest manner of working, and involving less loss of material. The reduction of chloride of silver by means of iron, zinc, or copper in an acid liquid is well known to be an unsatisfactory method, as the product is always found to be contaminated to a more or less degree with the metals employed; the same result occurs if the chloride of silver is reduced by means of copper in an ammonia solution. At the same time, no mention has ever been made of the employment of zinc to reduce the chloride out of the ammonia solution. The probable reason why such an experiment has not been made is on account of the analogy supposed to exist between the two metals, which seemed to promise identical results. As experience proves, however, a very different result is furnished by the employment of zinc, for by using this metal silver of a perfectly pure description may be obtained.

\* *Neues Jahrbuch für Pharmacie.*

In fact, the two bodies which act upon one another, the chloride of silver and metallic zinc, are placed under circumstances of a totally different character, as when chloride of silver in a solid condition is brought into contact with zinc in a similar state, in the presence of a free acid. As both bodies act upon one another in a compact condition, the silver is also separated in a like state, and it is well known that fused chloride of silver, reduced by means of zinc, furnishes an adherent mass of metallic silver. During the operation the zinc continues to be dissolved by the free acid, and it is not impossible that this second chemical action, which goes on at the same time, has the effect of again reducing the zinc in the silver, and, both being combined, the acid containing free zinc is powerless to act upon them. If, however, the chloride of silver is present in an ammoniacal solution, therefore, without any cohesion of its finest particles, the metal is separated in an exceedingly loose manner, having the appearance of a very delicate sponge, and at the same time only so much of the zinc is dissolved as there is chlorine given off from the silver. In reality, however, the operation is not so simple as it at first appears to be; for, on the one hand, the zinc becomes covered, during the process of reduction, with a white powder (oxide of zinc), which, on being agitated, becomes dissolved in the ammonia; and, on the other hand, the reduced silver assumes a dark colour from contact with the zinc, which, however, disappears on its being shaken, the product then becoming of a light grey colour. Occasionally a somewhat energetic generation of gas takes place during the operation; whether the same consists of nitrogen or hydrogen I have not yet determined.

In order to reduce chloride of silver by means of zinc, it is first dissolved in ammonia and placed in a bottle, and pure zinc in small excess and in fragments of notable size (so that it may be easily separated after the process of reduction) is then added. The decomposition commences at once, and proceeds so rapidly, especially if the vessel is well agitated, that in the space of three hours a quarter of a pound of chloride of silver may be reduced; the duration of the operation depends, however, of course, on the greater or less excess of zinc present in the solution. A certain excess of ammonia will likewise have the effect of accelerating the operation. At first the precipitated silver assumes a light grey or dirty white colour, but towards the end it becomes dark grey or even black. A few drops of the ammoniacal solution should be examined in a test-tube from time to time, and precipitated with hydrochloric acid; the operation is at an end when no turbidity is apparent on the addition of the acid. When this is the case, the precipitate is allowed to settle down, and the clear liquid then poured off as completely as possible; the silver in the glass vessel is treated again and again with fresh water until all smell of ammonia has disappeared, and is then transferred to another bottle by means of a funnel, the tube of which has previously been stopped with a few fragments of glass to prevent the pieces of zinc from passing through at the same time as the silver particles. The superabundant water is then decanted as completely as possible, and the precipitate treated with concentrated hydrochloric acid, in which it is allowed to digest until the dark-grey colour has given place to one of a dirty white. If the silver contains much water it is possible that it may not become white on a single treatment with the hydrochloric acid; in this case the liquid must be again poured off and a fresh quantity of acid added. By this means the silver may always be obtained of a white colour, and when the operation has advanced thus far the precipitate is repeatedly washed until the water poured off is only very slightly acid. The silver is then collected on a filter and well washed with distilled water; finally, a little dilute ammonia is poured on it, and it is again washed with water. This treatment is rendered necessary in order to remove any minute quantity of chloride of silver which may have been formed by the action of the concentrated hydrochloric acid, the latter sometimes containing small quantities of free chlorine.

The silver produced in this manner is of a very pure description; at any rate, I have never been able to detect the presence in it of any other metal. When dissolved in nitric acid, and precipitated with hydrochloric acid, a fluid is obtained which, when neutralized with carbonate of soda, does not become turbid by treatment either with ferrocyanide of potassium or alkaline carbonates. It assumes a brownish colour on the addition of sulphide of ammonium, owing to the presence of dissolved chloride of silver, but no precipitate is formed.

The expenditure of ammonia in the operation is, of course, not inconsiderable, but, as the greater portion of it may be recovered by distillation, the actual loss of the same is hardly appreciable. In working with large quantities of chloride of silver, economy may be exercised in the use of ammonia by reducing the chloride in several operations, so that the ammoniacal solution of chlorine and zinc, when freed from the silver, is again used to dissolve the chloride. This appears somewhat strange, but is evidently due, in part, to the presence of free ammonia, which exerts an action upon the chloride of silver only when the silver has been separated. Such a mode of proceeding would, however, occur only when manipulating with a considerable bulk of chloride of silver, for, in reducing small quantities, the necessary amount of water required to dissolve the chloride may easily be added.

In the same way, nitrate of silver dissolved in ammonia may also be reduced with zinc, perfectly pure silver being obtained; this result takes place even when the nitrate solution contains copper, as is very often the case. The copper, it is true, becomes reduced by the zinc in the ammoniacal solution, but only very slowly as compared with the silver, and hardly at all so long as a certain quantity of the latter is present in the solution. By this means I have been enabled to separate the whole of the silver from old coins containing but 25 per cent. of that metal. Every particle of silver must not, however, be separated, or, what is the same thing, the quantity of zinc added should be insufficient to precipitate the whole of it. The process possesses the particular advantage that in order to separate copper from nitrate of silver it is not necessary to transform the latter into chloride before it can be reduced. The finely-divided silver must, however, be treated, in the manner described above, with concentrated hydrochloric acid, and afterwards well washed, to remove the particles of precipitated zinc. For the production of pure nitrate of silver this method is especially recommended, as, by its employment, the tedious operations of washing the chloride of silver and its subsequent reduction in crucibles are entirely dispensed with.

## RESEARCHES ON DRY PROCESSES.

BY M. CAREY LEA.\*

In the present paper I propose to describe two new dry processes of interest. One of them will be found, I think, very valuable; the other, though less generally useful, is the more curious of the two. I shall describe it first, and then pass to the other.

In the first of these processes all the usual manipulations of negative-making are omitted, except the first and last. To say that it is possible simply to collodionize a plate, and then, without further treatment of any kind, to place it in the slide and expose, and, some hours after, to open the slide and take out a finished negative ready for fixing, would seem to be affirming too much; yet it is not only possible, but extremely easy of execution. The simply collodionized plate develops itself spontaneously after exposure, so that the ordinary operations of sensitizing, washing, developing, &c., are all done away with—nothing is left but the collodionizing and fixing.

\* *Philadelphia Photographer.*

The process is as follows. A collodion is prepared according to this formula :—

Ether	...	...	...	8 ounces
Alcohol	...	...	...	8 "
Bromide of cadmium	...	...	128	grains
Bromide of ammonium	...	...	32	"
Pyroxylene	...	...	96	"

This collodion is preferable to that which I described in my previous paper; as in the first it is difficult, with strong alcohol and ether, to get so much bromide of ammonium into solution. As this is a very excellent collodion for the collodio-bromide process, I shall refer to it hereafter; I will designate it as *collodion B*. It contains 8 grains bromide of cadmium and 2 grains bromide of ammonium to the ounce, and (taking the equivalent of bromine as 80) it requires, for its exact equivalent of nitrate of silver, 13.47 grains of the latter per ounce.

This collodion should stand for a month before use, in order to ripen properly. It may be used at the end of a week, but slightly veiled negatives are then to be expected.

It is to be sensitized with nitrate of silver when wanted for use. In the present instance we distinguish two cases: where the plates are to be exposed immediately, or where they are to be kept some hours before exposure.

In the former case, where the plates are to be exposed immediately, add to the collodion 16 grains of nitrate of silver to each ounce of collodion. This nitrate is, of course, to be very finely pulverized; it is added to the collodion, well shaken, at intervals, for an hour, or two or three hours, and then let stand two or three hours to settle, or it may wait for twenty-four. Immediately before use, add to each ounce of collodion—

Gallic acid (60-grain solution in alcohol)	24 drops
Glycerine (pure concentrated)	... 20 "

The solution of gallic acid keeps indefinitely, but must have been filtered perfectly clean.

These substances are well stirred up with the collodion. I should have said that the portion to be thus operated upon should have been first decanted quietly from any sediment that had fallen by standing, after admixture with the nitrate of silver.

This preparation of the sensitive collodion is not in the least troublesome in practice. Up to the point of adding the gallic acid and glycerine it answers excellently for any other collodio-bromide process, so that, for those who work the collodio-bromide processes, the production of these plates is especially easy.

The sensitive collodion is poured on the plate after the latter has been edged with india-rubber dissolved in benzole. As soon as it has set, the plate is put into the slide, and exposed about four or five times as long as for a wet plate. The slide is then either put aside, or the plate is transferred to a plate-box, and left for an hour or two in the dark room, when a perfectly developed negative will be found, ready for fixing.

The effect of taking a developed negative out of the dark-slide has something almost magical about it to one thoroughly accustomed to regular photographic routine.

The plate will not usually suffer if left for ten or twelve hours after exposure in the slide. If insufficiently exposed it may, of course, be intensified by any of the usual methods.

In the above case, it has been supposed that the plate was to be exposed at once. But these plates can be made to keep several hours before exposure, by diminishing the proportion of silver, increasing that of glycerine, and adding a little glacial acetic acid, with, however, a decrease of sensitiveness.

Fourteen grains of nitrate of silver, very carefully weighed, is, in such case, the proper proportion. Add to each ounce—

Gallic acid (60-grain solution in alcohol)	20 drops
Glycerine (pure)	... 30 to 35 "
Glacial acetic acid	... 5 to 8 "

This collodion gives a bluish and transparent film, and needs wet blotting-paper at the back. The plate may wait two, or three, or sometimes four hours, before exposure, and several days after it, without injury.

The effect of exposure is curious enough. A plate prepared in the first described method, if kept for several hours without exposure, will fog all over; but if exposed at once, the setting in of the development checks the fogging propensities, and, at the end of ten or twelve hours, the plate is still perfectly clean.

The glycerine is useful, not merely to check the drying, but it checks the disposition to fog, at the same time somewhat diminishing the sensitiveness. If the glycerine be omitted, the plate, at the expiration of an hour or two, begins to dry through; this destroys the sensitiveness, and, even if the plate has been exposed before it sets in, the development ceases as fast as the drying advances.

The process which I shall next describe, though less curious than the foregoing, will be found more generally useful. It also owes its activity to gallic acid, but differs essentially in all its other points.

The same collodion is to be employed, sensitized in the same way, with 16 grains of nitrate of silver to the ounce. When the sensitized collodion has reposed sufficiently, I decant a portion, and add to it a 60-grain solution of gallic acid, in the proportion of 25 drops to each ounce of collodion, stirring well up. Coat the plate, previously edged with solution of india-rubber, one or two grains to the ounce of benzole, and, as soon as it has set, place it under the tap and wash for four or five minutes; dry, and the plate is ready for use.

It will be seen that this process is analogous to that which I described in a previous paper, with the substitution of gallic acid for alcoholic solution of aloes.

The gallic acid process gives exceedingly soft and harmonious images. It is very sensitive, greatly more so than the ordinary run of dry processes. The negatives are clean, and the development very manageable. The process is intended either for alkaline or pyrogallie development, of course with a longer exposure in the latter case.

This last gallic acid process has impressed me most favorably. Its power of giving a pleasing rendering of strong contrasts is remarkable. For example: a building partly in sun and partly in shadow is rendered harmoniously, and without a harsh contrast between the lights and shadows. At this time of year, when the foliage is gone, and living myself, at this season, in the city, I have had no opportunity of trying it on trees, but such trials as I have made on objects presenting violent contrasts make me hope to get better effects of foliage by this than by any of the well-known dry processes hitherto in use that I have tried.

The process is, moreover, a very sensitive one. It seems, therefore, proper to remark that if, in consequence of over-exposure, any tendency to flatness is perceived in the alkaline development, it is better to wash off and intensify with acid, pyro, and silver. This can only be rendered necessary by a considerable over-exposure.

PS.—Since the above remarks were in type, on examining some of the self-developing plates prepared in the second manner—that is, with less nitrate of silver—I find that, even after several weeks' standing, they show no disposition to fog.

The conditions of this process are as follows: To obtain the highest sensitiveness a liberal excess of nitrate of silver is necessary; but, of course, its keeping qualities are correspondingly diminished. When there is not too much nitrate, the plates keep several hours before exposure, and appear to keep indefinitely after; for, as the drying goes on, any disposition to fog disappears, and thus the plate, after reaching its full development, shows no tendency to deteriorate, but may be kept until it is found convenient to finish it.

What is invaluable is, that even *exposure to light does not seem to affect it after it has become thoroughly dry*. Of

course, a plate so exposed could not be redeveloped before fixing, or the fresh latent influence of the exposure would doubtless cause it to fog all over; but in the absence of any such application of a new developer the plate seems scarcely to suffer by light; at least, one accidentally exposed for some time to light was not thereby visibly changed. This is important, because if the process should prove, on thorough trial, to answer well for landscape taking, the ability to keep the plate as long as may be convenient after exposure, without fixing or other treatment whatever, would be very valuable.

### TAX THE SUN

Our friend *Punch* has this week made a most diabolical—we beg his pardon, a most brilliant—suggestion. He proposes a tax on photographs! Unfortunately, the idea is not quite new, *Punch* himself having before proposed it. That was in the time of photographic prosperity; but, by some neglect of the Chancellor of the Exchequer, the suggestion was overlooked; and now, in the time of photographic depression, it would never do. In the United States such an impost exists; but it was a war-tax, and our American photographic brethren having been since struggling hard to get rid of it. We wish them success in the struggle for ridance; a struggle English photographers would have to imitate should *Punch's* hint be acted upon. Here is the proposition he makes to the Chancellor of the Exchequer:—

MY DEAR DISRAELI,—You told me the other night, at Lady Derby's party, that you were cutting some pretty figures for exhibition on the Budget night. I should like to help you.

Why, in the name of common sense, and Philistinism, and everything that is practical, don't you clap a penny tax on PHOTOGRAPHS?

I have mentioned it before, but as our friend Bright said last week, it is necessary in England to repeat a thing a great many times before it obtains attention.

There are about five millions of photographs made every year.

Do you know how much five millions of pennies make? Of course you don't, nor do I, nor does either of us know how to calculate it. Thank Fate, we were educated like gentlemen. But there must be some way of finding out, with decimals, or cubes, or hyperbolic loggerheads, or circular arks, or something.

Let us try at the problem. One hundred pence is eight-and-fourpence. I know that—you may take it from me. My little boy got an arithmetic prize (by the way, he will be a big boy one of these days, and then I shall be glad to talk to you about his future, should you be in office), and he assures me, positively, of this. I never knew him to tell a story (excuse a fond parental pride), and we may start upon that hypothesis.

Let us multiply that by ten. Ten times eight-and-fourpence is £4 3s. 4d., and that is a thousand pence. Well, a million is ten hundred thousand. O, bother, we shall never do it so. There must be some shorter way. Let us divide five millions by a penny, that seems simple. One in five—stop, that only brings us where we were before, like the American pig that thought it was getting out of the field through the pipe, only the pipe was crooked, and brought him in again.

Well, details are beneath great minds. I suppose you will allow that five million pence make a very large sum of money, which would look well among your pretty figures?

Get it, then, by enacting that no photograph shall be sold unless it bears an impressed stamp of one penny.

A photograph is surely a luxury. At least, people think it so, though the process of sitting for one is anything else.

Also, no one is obliged to buy one. Therefore, there is no hardship. Also, the Tax is so small that no one who can afford a photograph can feel the addition.

Also, the work of collection will be very easy. Let the Post Offices sell the stamped cards.

It is possible that a few of the touting blackguards who infest the streets, haul in customers, and fight for them, may be discouraged by the tax; but this, instead of being an evil, will be a very good thing. Humble and honest artists will buy their photograph stamps day by day as they do their letter stamps.

And you will, as aforesaid, get a very large sum in aid of your Abyssinian War and your other expenses.

Look to it, my dear Disraeli, and believe me, your affectionate friend,

PUNCH.

P.S. This will be taxing the Sun. He won't mind. He was very much hurt about the Window Tax, which shut out his light; but that is done away and forgotten. I—his moral Representative—answer for him.

## Proceedings of Societies.

### NORTH LONDON PHOTOGRAPHIC MEETING.

THE usual Monthly Meeting of the Society was held in Myddelton Hall on the evening of Wednesday, February 5th, Mr. W. W. KING in the chair.

The minutes of a former meeting having been read and confirmed, Messrs. Sidney Varden and E. S. Hall were elected members of the Society.

Mr. G. WHARTON SIMPSON read a paper on Glass for Photographic Purposes; and the changes of colour to which it is subject (see p. 75). At the conclusion of the paper he handed round for inspection a piece of sensitive paper which had been exposed under two samples of glass which Mr. Goslett had brought before the December meeting. The two pieces of glass had changed under the action of light from a colourless state, one to a yellow tint, the other to a lavender or purple. The latter, although much the darkest to appearance, transmitted the actinic rays freely, and the paper was nearly as darkly printed under it as where no glass intervened. The yellow tinted sample had obstructed the light considerably.

After some conversation, in which it was explained that Mr. Goslett, who had intended to have brought various samples of glass to illustrate the subject, was unavoidably absent, it was resolved to hear any observations members were prepared to make, and then adjourn the discussion to another meeting.

Mr. DALLMEYER said he had brought a few samples of glass with him, and might not be able to be present at the next meeting. His experience led him to believe that the glass least liable to change was English crown. Some samples of English plate glass were liable to exudation or "sweating." He had, on this account, tried some French glass, made by the St. Gobin Company, which he found free from this tendency. It was also very light in colour, as some examples he produced would illustrate. He believed that Mr. Chance could supply the photographer with a glass which did not change under the action of light. One of the chief causes of such change was, he believed, the presence of oxide of manganese, and also, in some cases, traces of sulphur. In making glass as hard as possible, and using a larger proportion of silica and lime, it was at times apt to devitrify; and to arrest this tendency manganese was used, which tended to cause subsequent change of colour. The important question was: What glass should the photographer use to secure as much as possible immunity from such change? He believed that crown glass was preferable to plate glass in this respect; the latter containing more alkali and being more subject to change. Mr. Chance had made a very fine crown glass, of which he now showed an example. It was much harder than usual samples, the density as compared with ordinary crown, being as 2.488 to 2.555. The price would be higher than usual; but he thought it would be better worth the price than many, as better resisting change. That the colourless glass was most apt to change was illustrated by an exceedingly beautiful sample shown in the Exhibition of 1851; some of which, secured by his late father-in-law, had, without much exposure, changed to a yellow tint, and quite lost its limpidity.

Mr. FOXLEE referred to a studio, in which he had worked some years ago, in which the glass had changed in a few months to an extent which made the exposures much longer. It was a sample made by Chance for studios. Some Belgian sheet, of a pale bluish green, was the best for studios which he knew. He believed that the presence of moisture aided in bringing about the change in some samples of glass.

Mr. BLANCHARD referred to some glass he had examined at the Thames Plate Glass Insurance Company's premises, which had been cut up for printing frames from broken windows. Under the putty it was a bluish green, whilst where it had been exposed to light it was of a decided brown tint, or yellowish green.

Mr. HART referred to some glass of an excellent light blue tint, which he saw at the Thames Plate Glass Works; but was told it was an accidental colour, not one they could rely on producing.

After some further conversation, in which Mr. Dallmeyer, Mr. Foxlee, Mr. Simpson, Mr. Hill, the Chairman (who pointed out the disadvantages of "Cathedral" glass), and some others took part, the discussion was adjourned.

Notice of some intended modifications of rules and nom

tions of officers for election at the annual meeting having been made, after some votes of thanks the proceedings terminated.

#### LONDON PHOTOGRAPHIC SOCIETY.

THE Annual Meeting of the Society was held at the Architectural Gallery in Conduit Street, on the evening of Tuesday, February 11th. Mr. GLAISHER, Vice-President, occupied the chair.

The minutes of a preceding meeting having been read and confirmed,

The CHAIRMAN said that at the last meeting he had to express his own deep regret, and that of the Society, at the loss of Mr. Claudet. Since then another serious calamity had followed, in the destruction of Mr. Claudet's studio by fire, containing many records and examples of interest, the loss of which was irreparable. Again, also, he had to express his regret at other losses. One of their number, an esteemed member of the Society and of the Council, Mr. Thurston Thompson, had gone. They had also lost Sir David Brewster, a name which could never be mentioned without honour and esteem, whose death caused a loss to science at large. In addressing the members at an annual meeting he regretted that his illness had kept him away for so long a time; but although the Society was, in some respects, as satisfactory as might be desired, it had done much in promoting the art, and would yet do more, and there were many hopeful features connected with it. In its early days, when it was a matter of fashion to patronize photography and belong to the Society, money came in very freely, as might be readily understood when £200 a year was paid to its Secretary. They had for some time past had the same expenses after the support of fashion had ceased, but he now believed that they were in a more promising condition. Now was, he thought, the turning-point in its history, and it would, he believed and hoped, continue to aid and promote the progress of photography. He then proceeded to read the Report of the Council, which we shall publish in our next.

The reception and adoption of the Report having been proposed, seconded, and carried,

The CHAIRMAN said, that as no nomination for officers had been made, except those of the Council at the December meeting, the following gentlemen would be elected or re-elected to office:—Sir Frederick Pollock, as President; the Rev. J. B. Reade, as Vice-President; Mr. W. Morgan Brown, the Earl of Caithness, Mr. John Spiller, Mr. Russell Manners Gordon, as members of Council. In place of Mr. Claudet and Mr. Thurston Thompson, deceased, Mr. Henry Claudet and Mr. Valentine Blanchard were proposed and elected as members of Council.

The Treasurer's and Auditor's report were read, and would be published in the Society's journal.

Mr. Oliver Sarouy, of Scarborough, proposed by Mr. Wharton Simpson, and seconded by Mr. H. P. Robinson, Mr. Glaisher, and Rev. J. B. Reade, was elected a member of the Society.

The CHAIRMAN passed round for examination a portrait of Mr. Durham by M. Adam-Salomon.

Mr. SOLOMON then exhibited his apparatus for enlarging by means of the magnesium light, and, with the assistance of Mr. Allen, produced a very excellent enlargement, which was slightly over-exposed with an exposure of thirty-five seconds; the amount of magnesium ribbon burnt costing, as the Chairman explained, about one halfpenny, as a yard of the ribbon, costing threepence, burnt three minutes.

Mr. J. R. JOHNSON then read a paper on the Treatment of Disordered Baths, in which he detailed the advantage of the use of permanganate of potash in oxidizing and removing organic matter.

After some remarks from the Chairman on the interest of the paper, and on the success of Mr. Solomon's enlarging apparatus,

Mr. DUNMORE read a brief paper on the Advantages of Using a Concentrated Light, and exhibited some specimens characterized by vigorous light and shade, in some respects resembling the effects in portraits by M. Adam-Salomon.

After some conversation, and votes of thanks to Mr. Solomon, Mr. Johnson, and Mr. Dunmore, the proceedings terminated.

## Correspondence.

### M. SALOMON'S PORTRAITS.

DEAR SIR,—I have read with very great interest the accounts of your visits to the studio of M. Salomon, and it is to be hoped that English photographers will derive great benefit from your lucid explanations of the method of working pursued at the celebrated establishment in Paris.

M. Salomon is undoubtedly an artist in every sense of the word; hence the superiority of the results he obtains. The same description of studio, apparatus, material, &c., can be obtained by most practitioners of photography. Let them use them, and endeavour to take a few lessons from this master of the art. Let us hear no more prating about all sorts of dodges, coloured collodion, and the like. Let us try to approach, if we cannot surpass, the work of M. Salomon. Let us follow, although a Frenchman shows the way.—I am, dear sir, yours very truly, A. H.

*Plymouth, February 10th, 1868.*

[We publish this letter because its spirit is one we should be glad to see carried out by all photographers. A spirit of emulation is always productive of excellence.—Ed.]

## Talk in the Studio.

A REMARKABLE NATURAL BRINE.—On a recent occasion Dr. J. Attfield exhibited and described a sample of water from Jamaica which had a very unusual constitution. A gallon of the water contained—

Chloride of calcium	...	...	1,500 grains
Chloride of sodium	...	...	1,000 "
Chloride of ammonium	...	...	2½ "

The taste of the water was peculiar, and, upon evaporation, it left a deliquescent residuum, which attracted moisture from the air even faster than the mixture of chlorides of magnesium and sodium ordinarily obtained from sea water. Such a quantity of water would be but ill-fitted for photographic use, and negative films washed with it would be left in a hygrometric condition, easily assailable by the slightest touch of frost. This circumstance might furnish a practical answer to the doctrine lately promulgated.

CHLORIDE OF SILVER BATTERY.—A new construction of voltaic battery, which, considering its small size, gives very great indications of power, was exhibited conjointly by Dr. Warren de la Rue and Dr. Hugo Muller at the meeting of the Chemical Society on the 6th instant. Its novelty consists in the use of chloride of silver fused around a thin silver wire as the negative element, the positive plate being composed of a small rod of zinc which need not be amalgamated. The size of the whole arrangement does not exceed three inches in height, and, with a battery of ten cells excited with salt water, a rapid current of mixed oxygen and hydrogen gases was evolved from acidulated water. When in use the salt brine becomes gradually charged with chloride of zinc, which tends to increase the energy of the battery, and the whole arrangement continues in working order until metallic zinc begins to be deposited on the negative element, when the exciting liquid must be changed. For convenience in putting into action the whole series at once, the round bars of zinc and chloride of silver are fastened at the top to a wooden frame which is made to slide upon glass uprights, and, when immersed, the white chloride is, of course, undergoing a slow reduction to metallic silver, which permeates the mass much after the fashion of the strings of virgin silver that are not unfrequently met with in nature, and are believed to have a similar galvanic origin. Messrs. De la Rue and Muller are having made for further trial a battery of two hundred cells.

PORTRAIT FIGURES WITH NATURAL BACKGROUNDS.—Our notice of Mr. Edge's cards has elicited many ingenious suggestions on the subject of double printing. Referring to the subject generally, the Editor of the *Scientific American* says:—"We have seen equestrian photographs beautifully done in this way.

The photographer arranges in his studio a wooden rail of the right height, on which a side saddle is placed, and the lady, dressed in equestrian costume, mounts, takes position as in riding, and is duly photographed. A paper print of this negative is then made, out of which her figure is carefully cut, blacked, and pasted upon the engraving of any handsome steed that the lady chooses to select. A negative of the horse is then made which has a blank space corresponding to the figure of the lady. Two printings are required to produce the picture: one from the negative of the lady, the other from that of the horse. Instead of engravings, photographs from living animals may be used.

**COST OF DISTILLED WATER.**—A sensational statement recently appeared in the *Pall Mall Gazette*, to the effect that the distilled water used by the Abyssinian Expedition cost two shillings per gallon, and amounted to £4,000 per day. A naval officer writes to point out its exaggeration, and says:—"In our ships of war, even under unfavourable circumstances, one ton of coal may be depended upon to produce at least ten tons of distilled water. With coal at £1 a ton the price of distilled water would be two shillings per ton. Probably at Zoulla Bay each ton of coals may cost £3, at which rate a ton of water would cost six shillings, making the price per gallon more nearly a farthing than a halfpenny."

## To Correspondents.

**MERCURY.**—The operation of transferring the image to a lithographic stone after you have produced the image in bichromated gelatine and covered it with ink is a simple one; but as it requires manipular skill, it is generally effected by a professional lithographer. The image, having been produced ready for transfer, is placed on the prepared stone, and then run through the press, the ink leaving the gelatine and attaching itself to the stone. The stones, &c., can be obtained of various dealers in such materials.

**W. W. (Newcastle-on-Tyne).**—Your canopy A should be placed at a right angle with the background, and you will not then need the extension B. Your lens is not apparently a good one; and, in any case, it is too short in focus for standing figures in card pictures. If you study the articles on *Pictorial Effect* which we are now publishing from week to week you will improve in posing.

**D. S.**—Any good lens, or quarter-plate lens, will serve for enlarging in the method we described of camera printing on collodion. Regarding landscape photography, it is difficult to recommend any especial course. A few men succeed perfectly with dry plates, but more succeed with the wet; and unless you are quite certain of your process and manipulations with dry plates, it is safer to use the wet process, as in that case you see the result at once, and if one plate fail you proceed to try another. It is equally impossible to say which is the best kind of tent, lens, &c., as so much depends on the kind of work you wish to attempt. Consult our advertising pages, and if you wish for information on any special point, state the details clearly, and we will advise you.

**B. R. S.**—You are right. The paragraph relating to the use of carbolic acid for mounting materials, accredited to the *English Mechanic*, is an extract from one of our own articles, made without acknowledgment.

**ANTI-CHIGNON.**—The chignon head-dress is doubtless rather troublesome to the operator; but with a head-rest, which can be adapted to different positions and different forms of head, it is generally possible to place the rest so as to form a support to the lower part of the head, just underneath the chignon. The card you enclose is exceedingly good, but just a little too deeply printed.

**SICK BATH.**—It is probable that you have made the bath too strong, and have not added sufficient nitric acid. It does not require iodide of potassium. There is no mode in which you can readily ascertain the purity of your distilled water without trying it. The salt of alumina used by Mr. Bird for purifying water is ter-sulphate of alumina; it can doubtless be obtained of any manufacturing chemist. You will find details on page 440 of our Tenth Volume.

**W. J. A. G.**—If we had been using tinfoil for a mask, we should certainly have lined it with paper, as, on bringing a metallic substance almost in contact with free nitrate of silver on the paper, we should expect decomposition and stains. 2. The stains on print No. 2 may arise from many causes. It may be that the bath is out of order, it may be dirty plates, or other causes; but the mere sight of a print is not a sufficient guide to

enable us to say what is the cause. 3. There is no absolute rule for the distance of the figure from the background: about two or three feet will answer. 4. If you attempt to intensify by means of your iron developer, with a few drops of silver added, the developer must be one containing sufficient of a restraining agent, either acid, gelatine, or suitable material to permit such addition of silver without decomposition. 5. The deep colour of collodion is due to free iodine, either added or liberated from the iodide. 6. Collodio-bromide of silver, if properly made, ought to have an opaline appearance, and be free from the granulation you describe when poured on a plate. The sensitive preparation will keep for a time; but is better tolerably freshly mixed. The *Philadelphia Photographer* can be obtained of Trubner, Paternoster Row.

**J. W.**—Very good for a first attempt; but there has been a trace of foggy deposit on the negative, we fancy. If you had painted the back of the plate, or used wet red blotting-paper in contact with it, you would have avoided the spreading of light by reflection where the window is.

**W. FISHER.**—It is impossible to say which position the sitter should face without having the design of the studio before us, as so much depends on the direction from which the best light is obtained; but speaking in the abstract, without relation to circumstances, which may modify the matter, facing the north-east is better than facing the south-west.

**J. H. T.**—On the whole, the subject is well chosen; and composes well. As a picture, it would be ruined without the chapel; it is also improved by the hedge, although, had it been quite under control, a little less of the hedge would have been better, as the interest it possesses scarcely justifies the space it occupies and the prominence it receives. The chief fault in the picture is that the middle distance and distance have little, if any, difference in their rendering, all after the immediate foreground being of one tint. 2. The best plan, in the case you describe, is to clean off the varnish with spirit, and begin again.

**R. S.**—A variety of causes may tend to produce the sunken effect and lack of surface vigour in a developed print, and also the want of purity in the whites. The paper itself, and the mode of preparing it, materially affect the result. An English paper, with hard size, gives the most vigorous picture. If an ordinary photographic paper be employed, a little gelatine in the salting solution is often of service. The use of iodides without chlorides tends to produce pictures lacking surface, vigour, and clearness. Of course the paper has two sides, and if you float the paper on the silver bath with the side in contact which was not in contact with the salting bath, the image is sure to be buried. The presence of any diffused light in the dark room is a frequent cause of lack of purity in the whites. There is no appearance of under-exposure in the print you send, but the negative is apparently a little too vigorous for such work. Development printing always requires a little experience and judgment to succeed with any degree of satisfaction, and the prints rarely equal in brilliancy those direct from negatives. As a rule, they require retouching to produce the best results.

**X. Y. Z.**—That marked A will answer your purpose best, and will serve both for copying and architecture. It will give straight lines, and is more rapid than the other you name. One the focal length of which equals the base-line of the size of picture required will suit you.

**GLASSHOUSE.**—In the position you describe, either a ridge-roof, with side and skylight facing north, or a lean-to building, with similar lighting, will answer; but decidedly avoid the slant fronting light to which you refer, which is much more inconvenient to manage. 2. Decidedly No. 1 of those you name.

**HYPO.**—A facetious correspondent asks us what articles, besides photographic prints, are best when entirely freed from hypo. We presume critical articles: few people like anything hypocritical.

**Mr. Bovey's** first article on Silver Printing, and several other articles in type, are unavoidably left over.

Several Correspondents in our next.

### PERMANGANATE OF POTASH FOR RECTIFYING OLD BATHS.

At the recent meeting of the Photographic Society Mr. J. R. Johnson read some interesting notes of an experiment with permanganate of potash, used for the purpose of removing organic matter in an old negative bath. The value of this permanganate for purifying water containing traces of organic matter has been for some time well known; and the experiments of Mr. Crookes, described in our pages twelve months ago, in which the value of permanganate of silver as a means of purifying water for photographic purposes was demonstrated, called the attention of photographers more especially to the subject. As this salt was not, however, commonly found in commerce, it did not come into general photographic use.

Mr. Johnson takes the well-known salt, permanganate of potash, which Mr. Condy has made familiar as a water purifier, and adds it to the disordered bath, and, so far as his experiments have gone, with the completest success. When permanganate of potash is added to water containing organic matter, all the constituents of such matter are changed by the oxidizing action of the permanganic acid; the hydrogen is converted into water, the carbon into carbonic acid, and any trace of nitrogen into nitric acid. The permanganic acid, robbed of oxygen and reduced to sesquioxide of manganese, is precipitated as a brown powder. The potash which was combined with the permanganic acid is liberated in a caustic state, and combines with any carbonic acid or nitric acid which may have been formed. When permanganate of potash is added to a nitrate bath it is probable that similar reactions will follow; and as the common organic accumulation in an old bath is alcohol, and the reaction between permanganic acid and alcohol is very rapid and complete, a ready means of removing this accumulation from the bath is here furnished.

The operation is analogous to the common method of removing organic matter by sunning, and furnishes a rapid mode of effecting the same thing without waiting for sunlight. In sunning a bath, which is, of course, first neutralized or made alkaline, the oxide of silver under the action of light gives up its oxygen to the organic matter, producing a similar result, slowly, to that produced by permanganic acid at once.

The chief risk attending this process is the production of alkalinity from the carbonate of potash formed in the course of the reactions. This is, however, a point easily ascertained and remedied. If excess of permanganate be added, it would result in the formation of permanganate of silver, which would be precipitated and filtered out, merely weakening the bath a little, and leaving nitrate of potash in solution.

Pure permanganate of potash is readily procurable in

commerce, in well-defined needle-shaped crystals of dark purple colour. It is sometimes sold in the form of a greyish powder: this is generally very impure. It is soluble in sixteen parts of water, but is generally used in a 20-grain solution, which is of a red purple colour. When added to water containing organic matter it rapidly loses its colour; it should be added a little at a time until a faint pink tint remains for some time, the permanence of this colouration indicating that the necessary reactions are completed, and all the organic matter oxidized.

Permanganates are somewhat sensitive to light; but no special photographic use has hitherto been made of them. It is possible that, in the final washing water, they might be found valuable in oxidizing final traces of hyposulphites, and converting them into harmless sulphates.

### MR. McLACHLAN'S DISCOVERY.

We have recently had an opportunity of conversing at some length with Mr. McLachlan regarding his alleged discovery, and ascertained some particulars regarding it. His great aim has been to discover the rationale of the collodion process, and to ascertain not merely that certain results were the usual sequences of certain acts, but why they followed, and what were the causes in operation, so that a failure once incurred, its source being known, it might be effectually avoided in future; and a success once obtained, its causes being thoroughly understood, it might be certainly and unerringly obtained for any number of times afterwards. In short, he has endeavoured to rise from the rule-of-thumb operations which he believes to prevail in photography, into practice based on principle.

He believes that he has succeeded in this, and has, for the last two years, been putting a discovery then made to the test. He believes that he can succeed steadily and certainly in all the operations of producing a negative, keeping his preparations for any length of time, and for any number of plates, in absolutely certain working condition. This success he states to be based on principle; but although certain formulæ are most conducive to success, yet absolute success depends on the use of "brains": judgment in the application of the principle and the use of the formulæ is necessary. How far this fact may place a limit on the value of the discovery we leave readers to determine for themselves.

In making his appeal through the journals for investigation, he was desirous of making sure of certain things. He wanted examination from capable persons free from the possibility of prejudice; he was conscious that he incurred risk of the suspicion of some and the ridicule of others; but he was willing to submit to this for what he believed to be the good of the photographic community. He was willing

to forego all pecuniary reward for disclosing his secret, notwithstanding many offers of purchase; but he was anxious that whatever credit might be due to the discovery might be fairly accorded to him.

This was natural; but, after all, it led to a somewhat false position. An appeal was made for competent examiners; but they must be free from the possibility of prejudice or prepossession, or of risk of unconsciously using Mr. McLachlan's ideas. One gentleman whom we know to be perhaps of all men in England the best fitted for the task—his qualifications as a man of science, as a scholar, as a non-professional photographer, and as a gentleman of high social position, being beyond challenge—was judged unsuitable because he was supposed to be a contributor to some of the journals, and might be committed to certain views on the one hand; or might, on the other, although pledged to confidence, find it impossible to write without making use of the ideas communicated by Mr. McLachlan. We pointed out that the gentleman in question was in nowise connected with any journal, but when he had a suggestion to make to photographers necessarily made it through one of the recognized channels of information, and that the highest scientific authorities, such as Sir John Herschel, would be open to a similar objection. This Mr. McLachlan saw, and admitted his position to be untenable, and that his views of a court of appeal must be modified. We mention the circumstance to illustrate the difficulties arising out of the position he has felt it desirable to assume.

Acting under modified views, Mr. McLachlan accepted a suggestion made at a social gathering of photographers. On Wednesday, the 12th, he had an interview with two gentlemen in London, Mr. Spiller and Mr. Peter Le Neve Foster, for the purpose of explaining to them, in confidence, the principles upon which his discovery was based. After some experiment these gentlemen will report as to results. What the next step in the matter may be, or when the public will be made recipients of Mr. McLachlan's confidence, remains yet to be determined.

## PHOTOGRAPHIC PRINTING IN SILVER, THEORETICAL AND PRACTICAL.

BY W. T. BOVEY.

### PREFATORY REMARKS.

"CAN anything new be written on the subject of printing and toning?" is a query that suggests itself most intrusively as I resume my pen to enter once more on a well-worn topic, which a truly formidable array of hints, formulæ, and minute directions would seem to have rendered completely threadbare, so far as teachings by the pen-and-ink process are concerned. But a heavy file of letters before me at this moment afford incontrovertible proofs that photographers have received instructions from indifferently qualified teachers, or they themselves belong to the numerous race of dullards. From north, east, south, and west have those silent messengers (now together impaled) come to inquire somewhat concerning printing matters: "The best formulæ for a sensitising bath?" "How long the time of floating requisite?" "Why the toning solution works so tardily?" "The reason why the toning bath has taken a fit of silks or laziness, and won't tone at all?" "The cause of small, yellow spots appearing in the prints after fixing, required?" "How to prevent bleaching?" "How to get the richest of prints" from the poorest among negatives? "How to secure black, blue, brown, warm purple, cold grey," and heaven knows how many other tones? And ten thousand laments seem to be concentrated in one general cry—"Oh, for a really reliable and uniform paper! Can you help us?" These, with many other questions of a similar character, afford ample proof that photographers have still much to learn, and need further assistance to enable them to overcome their printing difficulties; therefore, in the absence of a better qualified preceptor, I have, after much hesitation and contending cogitations over the matter, consented to brave malicious

commentators (if such there be), by writing a progressive series of papers, which will describe the *modus operandi* and the reason why of every move, in language sufficiently plain to enable all concerned, by moderate study, to rid them of their printing failings and failures.

A cursory glance over the matter would cause it to appear somewhat incomprehensible that, after so many years of active, practical experience in printing and toning operations, widespread ignorance, both of practice and theory, continues to cling, like a noxious parasite, to the art of photography. But to myself, who, in the capacity of a "journeyman printer" of no inconsiderable experience, have worked behind the scenes, the problem is one that works out its own solution. Professors of the "light art" (gentlemen operators), as a rule, entertain a decided contempt for "mere printers," whose usual workshops are mouldy attics, sloppy washhouses, deserted out-buildings, and grimy coal-cellars (remember, I have the authority of personal experience to bear me out in my statements). Somewhat *a la mode Calcraft*, with head nearly touching the horizontal "rafters," and body, to the waist, protruding through a trap door, I have stood on a ladder sensitizing paper. I have toned prints in a crazy, tumble-down shed, where my intrusive movements were suspiciously watched by the winking eyes of half-a-dozen sleepy barn fowls. More recently I superintended the printing department of a leading west-end house; said department being conducted in an unstalled stable. When occupied in the work of printing I have been sent to the roof above, and consigned to a foul court beneath. Ofttimes at a window have I stood, far above the pavement, and have clutched convulsively at the quivering printing-frames, as each wild blast threatened to wrest them from my grasp; and I have breathed a silent wish that some good spirit would stand beneath and shout into the ears of unsuspecting passers-by, "For your head's sake, stand from under!" Aye, and when I have successfully grappled with difficulties more important than any above enumerated, I have smiled as the half-sneering sentence flitted through my mind, "Only a printer!" "Only a printer!" yet what an amount of diligent observation and intelligent study needed to enable that printer to understand the nature of his work, and unflinchingly to cope with its manifold difficulties; and the chief reason why so few competent hands undertake to qualify themselves for printers is because of the sorry reward that would await them. Except buoyed up by making his business a labour of love, the life of "only a printer" is cheerless indeed. No medals nor honours of any kind to awaken slumbering ambition. No word of commendation falls to his share when prizes are awarded, for his—beg pardon, all his employer's—work. He is placed on a level with an organ bellows blower—the operation creates the harmonies. What matter whether that broad shadow that breaks up the foreground of yon brilliant landscape picture is the result of judicious sunning? What matter if the transparent tints in the winding river are produced by like means? the negative is the be-all and end-all. Why allow a thought to descend as low as the "machine-like printer?" And photographers really expect competency to be obtained under such adverse conditions. Echo cries, Don't they wish they may get it? "My printer is so ignorant of his work!" exclaims the employer. "My printer" might, in most instances, consistently reply, so far as printing is concerned, Ditto. I have conversed on the subject with photographers of high, medium, and low standing, and I have no hesitation in stating that, with very few exceptions, they know next to nothing about it, and their failures are accounted for in two short sentences, "My ignorant printer;" "Tis that abominable paper."

This last quotation written by my pen might, perhaps, to some savour strongly of "shop." To such I would reply in all sincerity, "*Hon! soit qui mal y pense.*" I disputed the sweeping condemnations levied on paper long before I ever dreamed of becoming myself a dealer in the article, and I do not hesitate once again to reiterate, the paper is less at

fault than he who fails with it. There is not a respectable dealer in photographic papers who does not supply an article capable of yielding the best results if intelligently treated; and from my personal knowledge of several photographic paper manufacturers, I venture to affirm that to a man they are most pains-taking, and do their utmost to supply their customers with the best possible material. The fact of the matter is just that, as a rule, it is not the paper produces failures, it is ignorance of principles; want of that chemical knowledge which enables the manipulator to command uniform success; 'tis a slavish observance of formulæ; above all, 'tis the characteristic proueness of man to quarrel with his tools when his work turns out a failure. When I started as a printer some years ago, I began with a determination that on all occasions when failures occurred I would first attribute the cause to self-ignorance, the chemicals and paper when thoroughly convinced either was in the wrong; and it is with feelings of pride I record it, after years of anxious toil, laborious study, and extensive experimental research, the wisdom of my first determination has at length become evident; for what were once my masters and tormentors have now been reduced to the subordinate positions of servants, and my chief desire is to communicate my experience in a form that will enable readers of the most moderate capacity to conquer, even as by hard up-hill work I have conquered. Possibly the victory has won even late in the day; possibly silver printing may be on its last legs; I doubt it much, as the best that can be said of any other method is, "it is equal to a silver print." For general purposes I have no hesitation in declaring that no process yet discovered can in usefulness approach silver printing. The question of permanency is doubtless its weakest point, but I am inclined to think the evil has been greatly exaggerated. True, prints have been dipped in sulphurous compounds, and have, by such means, been deprived of their fair complexions; but folks are not in the habit of applying such a straining test to their pictures; they neither boil them, bake them, fume them, nor expose them to anything more injurious than the atmosphere they themselves breathe. "They turn yellowish, greenish, everything uglyish notwithstanding," methinks I hear the reader reply. Granted in some cases; but I feel bound to offer a good word for the much-abused silver process of printing. About twelve months ago I caused a number of prints to be pasted on the interior walls of a laundry. No preservative nor extra precaution of any kind having been taken, the prints referred to have for nearly one year been exposed to extremes of temperature; at short intervals to the reeking steam proceeding from dripping linen, and for many hours each week to the fumes arising from burning coke. At the present moment, apart from a faint coating of dust, no change is perceptible. The probable reason why silver prints so often deteriorate quickly will be shown in its proper place.

In conclusion, having in these my prefatory remarks unburthened my conscience, my next will commence the subject at its beginning, by treating on the papers and materials employed to render them serviceable to photography. And my readers must admit my honest intentions when I prove to them how absurd is that parrot-like exclamation, "O, that trash of paper!"

## ON NATURAL CLOUDS AND ATMOSPHERIC EFFECTS IN LANDSCAPE PHOTOGRAPHY.

BY NELSON K. CHERILL.

THE importance which attaches itself to the discussion of any point of photographic manipulation is usually in direct relation to the difficulties involved in such manipulation, and to the amount of skill on the part of the operator necessary to overcome them.

This remark will, I think, be found to apply with much force to the subject before us. That clouds are important to the picture, no one will for a moment deny; that they are but seldom seen, as a rule, in photographs, is manifest;

while it is, in my opinion, equally evident that this lack of cloud effects in the general run of photographs arises almost entirely, if not solely, from the difficulties which beset the photographer when he attempts to produce upon his sensitive plate the image of their quickly changing forms.

Hence, I think, the importance of discussing at length the various means by which clouds and cloud effects can be best obtained in landscape work.

Before I enter at length into the question of considering the various means whereby I have obtained successful results in taking clouds, &c., upon the same negative with the other parts of the landscape, I wish to enter a little into the question as to whether it is or is not necessary for the production of the best results in a pictorial and artistic point of view that the clouds be obtained on the same plate and at the same moment with the rest of the picture. To this I give as my unalterable opinion, that it is quite possible in many cases to obtain results as good, or better, with separate skies, than can be obtained with the natural skies which happened to exist at the moment of taking the picture; though, at the same time, there may be many cases in which it is not only desirable, but necessary, to take the clouds and all at one operation. Of course, when a picture is taken with a white sky, and clouds put in from another negative, the result must depend in great measure upon the art knowledge of the photographer, as well as upon his skill in effecting the mechanical part of the arrangement. The clouds used in such cases must be in proper harmony with the picture, and must not in any way disturb its balance of light and shade; also, they should be of as nearly as possible the same character as those which existed in the view when the other parts were secured. For instance, it would be very improper to represent huge masses of cumulus clouds in the sky of a picture taken under the serene and still aspect of a summer's early morning; not that it is impossible that such clouds might have existed in the sky at the time, but the effect of the picture would be inevitably spoiled by them; inasmuch so, that even if they were actually present in the sky, it is easily to be imagined that no artist would attempt the landscape till they had cleared away, and certainly no photographer wishing to represent the beauties of early morning would print in such clouds as those of which I have been speaking; he would rather have no clouds than the wrong ones. And it is only his art knowledge which can dictate which are the right and which the wrong ones. If there is, however, choice in the selection of clouds for any picture which has been done with a white sky, there is equally a choice in the selection of clouds for any picture which it is proposed to render all at once—sky and foreground at one operation—for it cannot be supposed that all skies are equally suited to any view, and it is hardly to be supposed that the sky and the view will remain for long exactly suited to each other. I know that there are cases—but these are, I think, more the exception than the rule—when for a whole day the clouds follow one another over some glorious landscape, each form, as it passes, seeming more splendid than all that preceded it, and each arrangement of effect seeming better suited to bring out the force and effect of the view. Then, of course, your photographer without art knowledge has nothing to do but to work away as hard as he can, and to obtain the most perfect results which his skill can command; but this is not always so. It is not always—I believe I am right in saying it is not often in this climate—that the clouds are at any particular time when it becomes more or less necessary to take the even sufficiently suitable to render it worth while to bring his about them one way or the other. When, however, as a sort of are constantly changing, in some aspects they are pictorially right, and in others, if not absolutely so, are far indifferent as to spoil the effect of the picture; and if the arrangement of these things and to judge them requires a glance, if that which nothing but art knowledge can strike the eye at once, rely

his choice of a sky, whether it be that he wants to take his pictures all at one operation, or whether he take them at two. No mechanical addition to the camera, no flapping of shutters nor crowing over other people's work, can compensate for the want of a calm, decided judgment, based upon a complete and thorough knowledge of art.

I mentioned, in the beginning of this paper, that though in many cases clouds might be printed in afterwards so as to produce as good an effect as if they had been taken in the original negative, there were also many cases in which it was necessary to take them at the same time with the rest of the picture.

I consider that these cases may be made out briefly as follows:—Whenever the sky-line of the picture is tolerably near and abrupt—as, for instance, in nine-tenths of the English landscape scenery, where the objects in the foreground or middle distance rise up to the sky-line, or where the hills or other distance may not be more than (say) a couple of miles distant—the line of demarcation is quite sufficiently well made out to enable a skilful operator to put in any suitable sky in such a manner that no one could tell whether it were joined or not. In all such cases I look upon it as optional to the photographer to produce the sky at the same time with the rest of the picture, or to leave it for a subsequent operation: his art knowledge being, of course, the guide to direct him as to which plan it will be best to adopt.

But, on the other hand, where the view is of a very extended character, and the distance of the horizon very great, the clouds become so mixed up, as it were, with the picture, that no double printing could serve to produce the best effects in an artistic point of view. No clouds but those which actually went to form the picture at the moment the lens was uncovered can be put in to do duty for the innumerable delicate gradations which they produce upon the forms of the distant view; not only by their shadows (for I look upon these as a matter of comparatively minor importance), but also by their being actually mixed up with the view, as I said before. The reason of this is evident: the clouds are suspended in the atmosphere at a very limited height from the earth—I do not know what exactly, but say, for argument, from 1,000 to 3,000 feet.\* Let us take the lower figure, as it will serve to illustrate my point the best, and the principle will hold good in all cases.

Let us, then, speak of clouds 1,000 feet from the earth. It will be evident, on a little consideration, that in a near view, the clouds and the landscape will be two different things suited to each other, it may be, but separate and distinct; the clouds will, as it were, be something held up behind the picture, something which may be altered without changing anything else in the picture. Now see how different the case will be with *very* distant views. There are many views in this country where the most distant point in the horizon is, perhaps, twenty, thirty, forty, or even fifty miles off. Now suppose that between the spectator and the farthest point of the horizon in such a long view as this there are clouds at various intervals at a height of about 1,000 feet. It will, I think, be seen at once how, by the natural law of perspective, they seem to come nearer and nearer to the earth as the distance increases towards the horizon; so that mountains, and even quite small hills, are apparently shrouded and veiled by them, when in reality they may not be so. Now this is just the effect which must be produced at *once* in the camera, or let alone; no amount of double printing can effect it, nor can any amount of dodging secure the representation of the true effect in any other way than by *concentric* photography. So, then, I conclude, that while in any and uniforn, which the clouds are *behind* the picture sought to be other question printing may and will suffice for the best photographers is necessary to produce the picture all at

assistance to enable the weather clouds, and not of rain clouds, ceptor, I have, after n consequently interfere with the view at a cogitations over the matter; tator.

one operation, when the clouds come in front of any part of it, or when they are in any way mixed up with it.

These remarks do not apply to what is usually known under the name of "atmospheric effect." I have been speaking of clouds as clouds, and not as mist, fog, or vapour. We all know that when clouds descend to the earth they look very different from what they did when high up in the air; and when clouds come down so as to form a palpable mist or rain upon the earth, the view is generally very much confined, seldom extending beyond a few miles. Also, under these circumstances, the clouds have but few grand effects suitable to the pencil of the artist or to the camera of the photographer. Storm-clouds, before or after rain, are almost always grand enough; but during the storm itself most men would prefer shelter to work. When the distance is, however, only involved in slight mist; when it looks atmospheric (or, as a friend of mine would call it, "mysterious"), and when it is not too distant—no "cloud forms" actually interfering with the outlines of the distance—sky can be put in by double printing; but it must always be borne in mind that the more distant the view the more difficult it will be to put in clouds with good effect by double printing, because they must be so very delicate, and the line of junction must be so exceedingly well managed not to show.

I had intended to finish up this first part of my paper by a few remarks upon cloud shadows, but I shall refrain from the subject, as Mr. Simpson's remark at a recent South London meeting so completely answers any objection which might be raised to the double printing for clouds, on account of the shadows being wrong. I would only add the further consideration that it is, as a rule, impossible to point out in any picture which shadow is made by any given cloud, and that, therefore, though it may not be strictly true to put one set of clouds and another set of shadows, if no one can detect the error who is to say where it exists? I would not for one moment, however, uphold any error in photographic works; I would much rather they were all done with absolute truth as well as with the best artistic effect; but I hold, and I think I shall carry the sense of the best men in the profession with me, that in such a case as I am now speaking of, a *slight error* in the representation of the cloud effect is better than a great departure from the requirements of art. I am of opinion that where one or other must be the case, it is better to have the shadows of the clouds in the picture too small (or, rather, too large), or slightly in the wrong place, than to have an arrangement of clouds which would be utterly inartistic and unsuitable to the character of the picture. In every case, as I have before said, there is no rule, but the simple capacity of the artist must serve to direct him in this as in all other matters of choice.

In my next I hope to set forth some of the means by which I have been enabled most successfully to render clouds in the same negative as the landscape; and in a future paper I shall hope to give some more suggestions as to double printing, with especial reference to the subject now under consideration.

#### PICTORIAL EFFECT IN PHOTOGRAPHY; BEING LESSONS IN COMPOSITION AND CHIAROSCURA FOR PHOTOGRAPHERS. BY H. P. ROBINSON. CHAPTER IV.

"It is quite singular how very little contrast will sometimes serve to make an entire group of forms interesting, which would otherwise have been valueless."—*Ruskin*.

"The arts themselves, as well as their varieties, are closely related to each other, and have a tendency to unite, and even lose themselves in each other; but herein lies the duty, the merit, the dignity of the true artist, that he knows how to separate that department in which he labours from the others, and, so far as may be, isolates it."—*Goethe*.

"Sounds which address the ear are lost and die  
In one short hour; but that which strikes the eye  
Lives long upon the mind; the faithful sight  
Engraves the image with a beam of light."—*Dr. Watts*.

"BECAUSE things seen are mightier than things heard," to quote Teunyson, and because an actual example visible to

the eye is better than pages of written words, I propose in this chapter to give a slight illustration how an artist, even in such a trivial sketch as the subject engraved on this page, conforms to the usages of art, and the value which his work gains by such treatment. I take this subject because it follows and illustrates the rule of balance given in the last chapter.

The two engravings represent the same subject—Windsor Castle—and are identical, with the exception that the sharp spots of black—the boat in the river and the bit of bank and tree—which appear in the one are removed in the other. It will be observed that the diagonal line starting in the

of dark in the foreground that this is the only possible form in which a landscape should compose. The principle may be applied in exactly the opposite manner: light may take the place of shade, and perform the same function. The picture may be generally dark, with a mass of light in the foreground by way of balance. For instance, the picture of a dark, gloomy castle may be relieved by a flood of light in the immediate foreground, breaking up and enlivening the otherwise monotonous shadows. Neither is it absolutely necessary that the landscape should rigidly follow the diagonal line; there are endless variations of the principle; but I give this, the plainest and most obvious of

all the rules of composition, first, because it is a key which, once mastered, will enable the student to unlock the secrets of the most complicated designs, and render his future studies easy.

As I proceed with my subject, I foresee that a little difficulty may possibly arise. The chief danger I appear to incur in writing definitely is that of being mistaken when I describe all pictures as composed in regular shapes such as the diagonal, pyramidal, circular, and similar forms; but it is only by this means that I am able to put anything tangible before the student, who, when he is sufficiently acquainted with formulae, and knows how to classify and combine them, may experiment with originality of composition upon his own account. As I said at the outset, rules are not intended as a set of fetters to cripple those who use them, and it is not intended that the student should absolutely abide by them. The object is to train his mind so that he may select with ease, and when he does select, know why one aspect of a subject is better than another. To some readers it may appear superfluous to thus look upon nature as a thing to be arranged

before any satisfaction can be derived from its contemplation, or from its representation; but when the student begins to analyse the cause of the beautiful and pleasing effect of some pictures, and the disagreeable effect of others, equally perfect as far as finish and manipulation is concerned, he will find that he can assign the reason to some agreement with the rules of art, however remote.

An attention to rules will assist the artist in keeping his picture in tune. The small mass of dark or light, whichever it may be, in the near parts of a landscape acts as a sort of keynote, as I have already said, and the pleasure good composition gives to the educated eye is not unlike that the ear derives from perfect harmonies in music; and if the arrangement of a picture is not obvious at a glance, if that which is equivalent to *melody* does not strike the eye at once, rely

Fig. 1.

Fig. 2.

and in his pictures, the point of dark, being placed near to and opposed to the point of greatest illumination, gives extreme value to his highest lights. The same method is almost invariably found in the landscapes of the Dutch school. In Turner's magnificent pictures of sea and sky the wonderful luminosity is, in a great measure, due to the darkest black being opposed to the highest light.

It is not necessary that the point of dark should consist of one object only; it is sometimes convenient to introduce a group of figures or a mass of rock; but it must always be remembered that a judiciously placed mass of dark in the foreground not only gives balance to the composition, but also increases the effect of the gradations of the middle and extreme distance.

It must not be supposed because I have spoken of a point

upon it that if the picture is pleasing, the composition is there, although it may be in a minor key. As music is only sound under governance of certain laws, so is pictorial effect only the combination of certain forms and lights and shadows, in like manner harmoniously brought together.

The moral to the landscape photographer is, that in many cases he must endeavour to obtain in his foreground some object or mass of objects that will act as a keynote to keep the whole in harmony; and if nature does not supply such object, the pictorial requirement may often, without violating material truth, be furnished by art. On this point more in another chapter.

### VISITS TO NOTEWORTHY STUDIOS.

#### MR. T. R. WILLIAMS' STUDIO.

WE invite our readers next to visit with us an English studio, where the work produced has long been with English photographers a favourite type of all that is at once delicate and perfect in modelling in photographic portraiture. None have ever surpassed, few have ever equalled, Mr. T. R. Williams in the exquisite delicacy, without feebleness or flatness, and the fastidious freedom from blemish which characterizes all his work.

We well remember a time—some ten or twelve years ago—which will be familiar to the memory of many London photographers, especially portraitists, when traditions of secret dodges were rife as the explanation of qualities at that time much rarer in photographic portraiture than now, a secret printing process was a favourite explanation, all the paper being, it was alleged, prepared by Mr. Williams' own hands, no assistant ever being permitted to penetrate the mystery; at a later period retouching was the favourite explanation; and we find, about four years ago, just after Mr. Williams had received a medal for portraiture at an exhibition of the Photographic Society, a published letter in which a correspondent asks if it be true that the "beautiful modelling and fleshy texture are due to the skilful artist rather than the photographer; and that use of wax or encaustic paste conceals all trace of colour, and even permits the picture to be sponged without detecting the presence

of the neutral tint employed?" It was true that Mr. Williams had pasted on the back of the frame duplicates of each picture exhibited, which permitted the opportunity of examination without an intervening glass; but this did not prevent the prevalence of the rumour in question, nor the statement in some quarters, not only that the pictures were touched, but the water-colour artist who had touched them admitted the fact. We have been forcibly reminded of these incidents recently, and also of how singularly history repeats itself.

Mr. Williams is one of the oldest as well as one of the most successful professional photographers, and one of the very few who commenced life with photographic portraiture as a profession upwards of a quarter of century ago. Having passed a few years in M. Claudet's studio, Mr. Williams subsequently initiated the practice of producing artistic groups for the stereoscope, and few things produced in photography have surpassed in beauty the charming Daguerreotype studies then produced, and which were eagerly bought by the public at a guinea each slide. Devoting himself at a later date solely to portraiture, his Daguerreotypes soon became famous for very similar qualities to those which now pre-eminently distinguish his paper pictures,—a singular brightness, and combination of the highest delicacy with great force and modelling.

Before entering the studio we may mention one or two instructive circumstances. Mr. Williams has never placed any pictures at his door, or, so far as we believe, made any kind of public announcement inviting patronage; but he has, nevertheless, always been one of the most fully employed portraitists in London, at the highest rates commanded by photographic portraiture. We mention this to enforce the lesson that excellence, not cheapness, is the true source of business success. Notwithstanding the race for cheapness which has been going on for years, Mr. Williams receives now, as he has always done, for six card portraits one guinea, and for six card vignettes one guinea and a half; a price at which the excellence of the work commands him the most extensive patronage.

We will now enter the studio in Regent Street, at the entrance of which we find Mr. Williams' name, but no

indication of his profession. In a comfortable reception room, quietly furnished in good taste, we find examples of the work. We are at once struck with the fact, that amidst the variety of good pictures, there is one speciality in which Mr. Williams excels; it consists of the whole plate portrait, head and bust vignettes. The examples are all especially beautiful, with an almost preternatural delicacy in the rendering of flesh, so free from harshness, rugosity, or coarseness, is every round and perfectly modelled head. We see but one or two specimens of enlarged work, and these are placed aside, as if scarcely intended for exhibition. A peculiar

refinement is the prevailing quality in Mr. Williams' work, to which the practice of enlargement would not readily lend itself, and it never appears to have found favour with Mr. Williams. There are some very well-coloured specimens about 10 by 8 and 12 by 10, those in oil being especially fine. The cards are also fine, and generally very brilliant and forcible. There are no scenic backgrounds, but some good accessories vary the effect of a plain background, and in many instances a cast shadow of the figure on the background gives much breadth and relief.

We will now ascend to the studio, and proceed to some

details of its construction and arrangement. The size of the room is about 30 feet long by 17 feet wide. As will be seen from the engraving, the chief light is from a skylight, sloping in direction of the length of the room, not, as in the ordinary ledge or lean-to roof, in direction of the width. The glass extends the whole width of the room, and backwards in the length of the room for nearly 20 feet, the exact measurement of the skylight being 19 feet 6 inches by 17 feet. The height of the room at the ridge is about 16 feet, and at the eaves a little over 8 feet. The panes at the end of the room are generally covered with blinds, so that without management of blinds or curtains the room would be lighted almost entirely with a skylight facing the south-west; this is, however, by skilful management of the blinds and arrangement of the sitter, generally converted practically into a high side-light.

The sitter and the camera are placed cross corner-wise of the room; two backgrounds, one facing each corner towards the light, being generally placed as fixtures. We omit in the diagram these and some other details which we shall describe to give a clear view of the interior. Moveable wings, covered with blue calico, are placed at each side of the background, and at times are made to cut off direct light, and at others to act as reflecting screens. The skylight is furnished with three sets of blinds, each set consisting of three blinds, one above another: one of dark blue calico, one of thick white calico, and another of thin white calico or jaconet muslin. By the judicious management of these blinds almost any effect of lighting can be obtained. The diagram illustrates a mode of arrangement we have seen in use. Over one-third of the skylight and half of the next third the dark blue blinds are drawn to exclude almost all light; over the other half of the middle section a white blind is drawn, and also over the upper half of the remaining third. One-sixth of the skylight, and that the portion most remote from the sitter, admits the light through clear glass; and this, if the sun were shining, would be covered with the thin muslin blind. It will be seen that the principal light is often virtually a concentrated high side-light, the concentration giving the effective cast shadows to which we have referred, whilst the amount of softened light admitted through blinds lights up the shadows, preventing blackness or hardness. Besides the blinds already described there are two other dark blinds which can, on occasion, be used. These are tolerably near to the head of the sitter, and can be used to prevent any vertical light reaching it. All the blinds are on spring rollers placed near the top of the skylight, and can be, of course, readily drawn so as to cover any required portion of the skylight.

The backgrounds are each provided with an arrangement which permits them to be thrown forward a little at the top, and so produce a graduated shadow on the upper portion. For convenience in photographing standing figures, behind each background is the base of a head-rest, screwed to the ground. An aperture in the background permits a rod, carrying the rest, to pass through, and so steady the head by means of an unseen rest. The backgrounds are of a dark grey, in flatted oil paint. One point neglected by too many photographers we may note in passing, is the use of a very light background for vignettes, which renders the production of a delicate gradation round the head and shoulders comparatively easy.

A moveable framework, forming, with a dark cloth thrown over it, a large dark canopy or tent, is used to shield the camera and lens from diffused light, and also to reduce the amount of illuminated atmosphere between the sitter and lens. The camera is also provided with a black velvet covered screen, put in front of the sensitive plate, with an aperture of the size of the picture, to protect it against the action of any stray traces of diffused light; no pains of any kind being spared to secure the plate from the action of any light but that intended to produce the picture.

In the production of the whole-plate vignettes, Mr. Williams for many years used a French lens with sufficient spherical aberration to give diffusion of focus and freedom from excessive sharpness. Of late he has used for the same purpose the patent lens with diffusion of focus arrangement, which tends at once to softness and depth of definition. A full exposure is invariably given to aid in securing immunity from coarseness or harshness of delineation, especially where any tendency to wrinkles, freckles, or coarse texture is present.

Our readers are already familiar with details of the mode of operating pursued by Mr. Williams, and we need here only briefly recapitulate a few particulars. A good commercial bromo-iodized collodion is employed, the products of various makers being used, and often in combination. A 40-grain nitrate bath for winter, and one of 30-grains for summer use, in each case containing a trace of nitric acid. A 15-grain solution of protosulphate of iron with 15 minims of acetic acid is used for development. An under-exposed negative would be intensified before fixing; but if the negative be—as care is taken that it shall be—fully exposed, it is fixed by immersion in a dipping bath containing a saturated solution of hyposulphite of soda. After thoroughly washing, it is intensified in daylight by means of a 1-grain solution of pyrogallie acid, containing 15 minims of acetic acid and a few drops of a 15-grain nitrate of silver solution. This is used with great care, so as to secure a few brilliant points of new deposit, giving intensity in the high lights only. The general tint of the negative is also rendered more non-actinic by this treatment, and sufficient printing value is thus secured. The finished negative contains minute points of high light very dense, minute traces of bare glass, and abundance of varying gradations of semi-transparency.

In the printing operations great care is used. For the vignettes an aperture, graduated by means of cotton wool, is made to suit each individual portrait, and so give the best result in each case. The acetate toning bath is employed. The prints are never suffered to remain in soak all night; four hours' washing, with frequent change of water, each print being drained as it is changed into fresh water, is considered, and doubtless is, much more effectual in removing traces of hypo, than protracted soaking in water.

Every first proof passes through Mr. Williams' own hand, and receives his instructions as to depth of printing and toning: modifications in the vignetting are suggested, and a pencil outline of the most suitable form is generally traced. Every finished print, as a rule, also passes through Mr. Williams' hand; each undergoes a fastidious scrutiny, and is rejected if it have a suspicion of a fault, either in depth, tone, or vignetting, as well as for any more tangible fault. The scrupulous care and educated eye which detects the minutest fault and rejects everything defective, as well as great skill and fine taste, have contributed much to the rare success which has attended the career of Mr. Williams as a portraitist, and rendered his pictures almost synonymes of photographic excellence.

Mr. Williams is a man of retiring habits, and rarely takes an active part in photographic discussion or communication; but his experience has always been placed freely at the service of photographers, as our readers know, but with what a ready and winning courtesy those who have come into personal intimacy with him only know. Although no believer in secret dodges, he has always been a careful experimentalist, and photographers are indebted to his suggestion, in the early days of the collodion process, for some of the operations—such as the direct iodizing of a new bath, &c.—which are now amongst the things of course in the order of working. We must now conclude our somewhat extended visit to one of the most interesting of London studios.

# OMNIUM GATHERUM: REMARKS ON VARIOUS PHOTOGRAPHIC TOPICS.

BY SAMUEL FRY.\*

It is a sonree of considerable pleasure to me to have this opportunity of again meeting with the South London Society, a body with whom it was in past years my lot to hold frequent and pleasant communion. The circumstances of my residing at a distance from town, and having engagements in an arduous branch of our common art, have debarred me, to an extent that is to me a subject of regret, of much pleasant society of days of yore. Do not, I pray you, suppose that I have come down here with some new invention, a fresh dodge, another wrinkle, far from it; I am simply here to hold a little converse with you on matters that interest us all alike. On some of these points hot disputes have arisen, on others misapprehension exists, on yet others our future course is veiled with the clouds of doubt and anxiety. Past, present, and future, then, it occurs to me that if, before finally coming to conclusions, we just sit down and come to some agreement as to the real meaning and significance of terms, of what is, and what should be, the actual object we hold in view, our progress may be advanced.

First, then, I think I violate no confidence when I relate as my primary theme the question which has now for so many years anxiously agitated the photographic breast: Can we make our pictures permanent? Gentlemen, whatever may be the answer to this question, I think we must consider that the numerous panacea which have been offered us to ensure it in future show a very strong doubt as to whether we have hitherto been very near it in our practice. Now I claim to be rather a practical photographer than a profound chemist, and I am strongly imbued with the belief that we have in our possession the means of making a photograph as 'permanent as there is any need it should be.

If people will, as I know they do, plunge masses of pictures wet with hypo into a water tank, and think because it has a syphon arrangement it is all right, they are sure to fade; and if they take them out and dry them in blotting-books for months together they will also very soon fade. I know a large establishment where this latter is done, and they go rapidly. But if, on the other hand, you use hypo once only, when the pictures are removed, have each one washed on a slab of slate or marble with a broad brush under a tap, and the whole lot well washed for five minutes before they go in the tank, and the same again three hours afterwards, and then be dried, I say emphatically, and I challenge contradiction, these prints will not fade. Are any such conditions as these generally observed? Not a bit of it. Hundreds of prints are daily put straight from the hypo into the water, and only taken out to be dried.

It is a fact, readily proved, that the greasy hypo fluid adhering to the prints cannot be removed by mere contact with water; but a mechanical appliance, such as a brush under a tap, instantly clears it away. Some may say, "What a while it will take!" but I hope to hurt no one's feelings when I say that if all be true that's repeated, a very few have such large batches of prints as to make the time thus occupied any object.

It is a startling evidence of the doubt that pervades men's minds on this important subject that now, in 1868, it is deliberately proposed, by good authorities, to return to the fixing and toning bath in one. It was an awful thing, and required some temerity to fairly put down in black and white such a proposition, and, strange to say, the idea is not scouted, for, from the latest experiments by Mr. Cherrill, using sulphate of ammonia with the toning and fixing solution, the picture can be demonstrated to contain a far smaller quantity of matter liable to change than has ever before been obtained. I have repeated and verified these experi-

ments, and hasten to express the pleasure with which I found that pictures thus fixed resisted the action of the potent fluid in which it was immersed; whilst an ordinary print, toned and fixed with hypo only, though washed with great care, immediately gave way. Perhaps we have here a happy issue out of all our affliction as regards permanence. The real question is in a nutshell: Have we greater permanence with separate toning and fixing than we had before? Some, who look upon fading as a natural sequence to printing, have conceived the thoroughly human idea that if we could not prevent, we might conceal, the fatal germ of death which seemed congenital to our productions, by enveloping them in a transparent coating of varnish or collodion. I have carefully tried these methods, and believe them worthless for the following reasons:—

Varnishes are composed of gums dissolved in certain spirituous or etherial fluids, and it is the aim of the maker to so blend his constituents in the liquid as to obtain a balance of focus between the elastic and the brittle gums, that, without anything like stickiness, there shall be elasticity to allow of contraction and expansion from atmospheric changes, and yet the hard transparency of more frangible vegetable gums. In their normal state varnishes are waterproof, but unless made very thick, and, therefore, opaque, will not long remain so, especially if the atmosphere have access to both sides. Handling, moisture, frequent change of temperature, even within moderate limit—within a very moderate period—destroy most varnishes, and they become friable, and, falling away as an impalpable powder, their uses are greatly diminished. Even where they do not thus act thus, time and light as surely yellows them as it does the leaves of autumn. Concentrated experiments to test the resistance of varnish are no criteria as to their value: the slow disintegrating influences I have mentioned cannot be thus estimated. It has been hinted that if the picture be mounted with india-rubber the print is hermetically sealed when varnished. I pray you dismiss any such idea. If you want permanence do not seek it by imprisoning your enemy: keep him out from the commencement.

There is strong reason to suppose india-rubber to be utterly worthless as a mountant; it is a vegetable gum, and exhibits the usual effects of atmosphere on such productions, losing its cohesion, and becoming a mere brown powder in a few years. Some have supposed india-rubber—as seen in commerce—to be the skin of the elephant and rhinoceros in a state of subdivision. This is not correct.

I pass now to collodion as a protective. I very carefully tried this, and had great hopes of it, but it itself turned yellow, and, exhibiting a surface partly smooth and partly rough, showed its protective power to be very uncertain; a few months made it quite pulverulent. But having thus referred to protective agents that are no protection, I will just advert to what I believe to be a most valuable protection, viz., an encaustic or ceramic pomade whose basis is pure white wax. We know white wax is permanent, because in Egypt and other countries, where it has been the practice to embalm or preserve bodies from destruction, the principal agent has been the cerecloth, which has not only resisted permanently the destructive effects of time to an unprecedented extent, but may be seen in the British Museum in a perfectly sound condition; whilst the varnishes, essences, and perfumed gums enclosed within the whole, although thus perfectly excluded from atmospheric influence, have utterly perished. White wax is a thoroughly reliable substance as a protective agent, and it is to a judicious application of it, in conjunction with certain mollifying ingredients communicating softness without greasiness to the preparation, that Salomon's pictures owe much beauty. The surface, and not only the surface, is proof permanently against fair usage, or the effect of moisture or vapour; besides which the effect on the picture is very valuable. It is not a gloss which is given; it is a rich liquid depth and enhancement of vigour and softness combined.

And now about carbon printing. This is, as far as we are

\* Read before the South London Photographic Society, February 13, 1868.

aware, permanent; we must not forget that there has been bichromate of potash used as a sensitizer, and that the whole picture is supported on a substratum of an organic nature which has been under the influence of this powerful chemical as a sensitizing agent. The tests employed to discover the presence of the destructive substances in silver prints are inert against carbon; and it has not yet been shown that there is left anything which can militate against its permanence; but it would be well to be quite clear on this matter. And now then, why, if carbon printing is thus permanent, if it unquestionably possesses that great virtue so long sought in vain; if, in a word, it is the solution of this great question of permanence, why is it not generally adopted? I ask this in no partisan spirit, but simply because it is a question continually put in any company where photographers meet. All admire the results, the full details are before the public, any one can purchase the materials, and no special commercial difficulties are imposed by the patentees. Why, then, is it unworked by the main body of photographers? I believe the primary cause to be that it is a blind process; you cannot watch the printing, and have to risk the results at the end of the day.

Mr. Cherrill, who has probably achieved as great success as any one in it, says it is the sort of thing to do your "best work in." If you want a thousand impressions, the negative may be learned by the actinometer, and good success obtained; but when, as is almost always the case, a heterogeneous batch of negatives are out printing, very small success has comparatively been required from each, and there seems difficulty in meeting the case.

Mr. Mayall states also that he is unable to print his small pictures economically by it. I do not mean cheaply, but on anything approaching a commercial scale.

In company where septs and arch-heretics sometimes congregate, I have heard the opinion often expressed that carbon in many cases fails to give the depth and brilliance of silver printing. From my own personal comparison of some of Bedford's choice landscapes in carbon and silver, the latter were far preferable. I have also a pair of Mr. Blanchard's celebrated "Scholar and Zealot," silver printed, which most agreed to be finer than the same in carbon. In discussing such a matter, we must remember we are only feeling our way, and that much has had to be *unsaid* in photography: where knowledge ends, there dogmatism too often begins. We have not yet seen the last of silver printing, nor are we likely to.

Just one more subject, and I have done. What about business? When these societies were established, most of the members were amateurs, but I fancy the professional element has of late years predominated. Great complaints are heard on all sides of slackness of business; but I sometimes think that if photographers were a little more versed in political economy they would perceive that not only is it no wonder our craft suffers, but that it suffers severely. Whether we recognize it or no, all businesses are subject to the immutable laws which regulate commerce—the laws of supply and demand; no artificial treatment has yet been able to create demand when the supply was excessive. Gentlemen, look around you at the state of every industry that can be named, and nothing but disaster can be seen. Look, again, at the number of professional photographers, enormously in excess of demand. The card mania called them into existence, and with the reduced demand came necessary depression. The issue of photographs, notwithstanding this, is more enormous than ever, and if any evidence were wanting to correct the erroneous assertion that the flatness of trade is owing to the public being aware that they are not permanent, it is supplied on a consideration of the immense numbers and various kinds now being used. Numbers of books are published; copies of works of art, collections of paintings from national galleries, are in daily increasing demand. I have good reason to believe that such quantities of paper, collodion, silver, and gold were never before used as now in producing photo-

graphs. But the demand for portraits has simply taken its natural position; unless a new mania arise, it will probably not be less than now, and it is evident that a fraction of the portraitists now existing will be required. But let no one think photography is going to the bad; its importance and value are more recognized daily; and in most of the important industries of the world it is usefully employed, for the simple reason that "truth," as embodied in photography, is recognised as a "household word."

#### A SUGGESTION FOR A NEW MODE OF TREATING AN OLD NEGATIVE BATH.

BY J. R. JOHNSON.\*

A GREAT Northern Wizard has promised the photographic world that by one stroke of his magic wand he will convert the collodion process, so delicate and uncertain in practice, even in the hands of experienced operators, into one absolutely definite and certain, so that a thousand negatives may be taken in succession without the risk of one failure.

Until this has been accomplished, any new fact which may tend, however slightly, towards this end will, I feel sure, be accepted by photographers with pleasure; and I make no apology therefore in calling the attention of the members present to one such fact which appears to me to have this tendency in not a slight but in a considerable degree.

It will, I think, be generally admitted that one of the chief sources of failure in the collodion process arises from the instability of the negative bath. That the bath should show this instability is not at all to be wondered at, inasmuch as it is undergoing a constant change of composition by the immersion of every fresh plate; the water holding the silver salt in solution becoming thereby gradually removed, and replaced by other fluids, viz., alcohol and ether. These are fluids whose elements enter readily into other combinations, but they are also necessarily more or less impure, containing small quantities of other analogous substances, and traces of oils, the nature of which varies according to the source from which the original wine or malt spirit employed in their production was obtained. We know well that when these fluids have accumulated to a certain extent, we find that the salt of silver becomes reduced without the action of light, and this reduction taking place over the whole surface of the picture, we have what we call "fog," and we fail then to produce vigorous negatives. Sometimes this reducing action takes place in the bath itself, when we have a deposit in an infinite state of division diffused through the bath, and showing but little signs of deposition, unless as a specular film on the sides of the vessel. When this is the case a few drops of cyanide of potassium, forming a clot of cyanide of silver, if well shaken with the silver solution, will entangle the attenuated matter in suspension, and will carry it to the bottom, thus clearing the bath, and removing the cause of fog. At other times the action is only shown on the iodized or bromized plate, the bath itself being clear and bright. In this case the cyanide appears to have no action; and I knew, until lately, no other way of clearing the bath from this source of fog than by rendering it alkaline and putting it in the sun. The action of light being added to that of the reducing agent, a portion of silver is deposited, while the reducing agent itself is destroyed, probably by oxidation, and the evil is cured.

About two months ago, Mr. W. Morgan Brown, Secretary to the late United Association of Photography, informed me that he had been troubled with a bad bath, and had tried several modes of curing it in vain, until, in his despair, he had put in a few drops of Condry's disinfecting fluid, when a complete cure was effected.

I paid but little attention to the matter at the time, but having read Mr. Crookes' excellent paper "Upon the Purification of Water by Permanganate of Silver," I was reminded

\* Read before the London Photographic Society, February 11, 1868.

of Mr. Brown's communication; and I determined to try whether the reducing agent of a fogging-bath might not be oxidized by the direct action of a permanganate, and, to my great satisfaction, the experiment was highly satisfactory. A few drops of a 20-grain solution of pure permanganate of potash added to an old bath first coloured it of a fine purple, which gradually changed to a turbid brownish hue completely removed by filtration. If the addition be made in sufficient quantity, the bath is completely cured of its foggy property, and a vigorous picture may again be obtained with it.

Not having a large stock of old bath at my disposal, my experiments have necessarily been limited, and, indeed, confined to one specimen of bath. Strictly speaking, therefore, it is only one form of the reducing agent to which my remarks refer, and the result may not be the same with other specimens of bath, in which the reducing tendency may arise from other kinds of collodion or from admixture of organic matter from other sources than the collodion. The experiments, however, of Mr. Brown and myself establish the fact that a permanganate may be used to oxidize organic matter in the bath without detriment to the remainder; and, as we know that the permanganate gives up its oxygen to all kinds of organic substances, there can, I think, be but little doubt that it will be found generally applicable. I have, therefore, hastened to communicate the fact at once, so that it may be tried by all photographers who read the record of our proceedings, trusting that they will give the suggestion a trial, and will report to us their results. More facts will be obtained in one week by this mode than an individual could acquire in many months' experimenting.

Before concluding, I would remark that, on mentioning the subject to Mr. Werge to-day, he informed me that Mr. Tully, of Sheffield, had for some time used permanganate of potash to clarify his printing baths instead of kaolin, and that Mr. W. had mentioned this fact to other photographers. We have here a perfectly analogous use of this substance, the substance oxidized and removed being, however, albumen or its derivatives which injure the positive bath, instead of the organic compound, or compounds, yielded by the alcohol or ether to the negative bath.

#### ANNUAL REPORT OF THE COUNCIL OF THE PHOTOGRAPHIC SOCIETY.

THE Council of the Photographic Society, in rendering its Annual Report to the members, feels considerable satisfaction that, after a year of unprecedented depression in many phases of the art of photography, it is able to congratulate the members on a more promising condition of the Society than has existed for some time, evidences of which may be found in the fact that a larger number of interesting communications have been brought before the members at meetings, and that an exceedingly successful exhibition has been held.

It is a source of congratulation that, during the fifteen years of its existence, the Society has, by the maintenance (at a large cost) of public exhibitions, by the founding and maintenance of a journal, which during many years was the only means of intercommunication amongst photographers, of announcing the continual progress of discovery and improvement, and of preserving a record of each step in advance made by the pioneers of the art, materially aided in placing it upon a solid basis, and contributed to the prosperity and advantage of all associated with photography, either as amateurs or engaged in its pursuit as a profession.

In looking at the general progress and present position of photography, and its now variously ramified applications, the Council cannot omit taking occasion to congratulate photographers on the solid advancement which has been made in their art. Prominent amongst the accomplished facts of the present day, which but a few years ago was amongst its hopes and aspirations, may be mentioned the discovery and working out to a practical issue, by one of the members, of a means of producing photographs in permanent pigments. Mr. Swan's carbon process, the announcement of which was first made to the Society four years ago, as then little more than an experi-

mental possibility, is now the means of issuing every week thousands of photographic prints as imperishable as the productions of the painter and engraver. Mr. Woodbury's process of photo-relief printing, also introduced by its inventor, a member of this Society, at a more recent period, is now also a means of producing, with the rapidity of the printing-press, permanent pictures, with great perfection and truthfulness of detail. Permanence in silver-printing has also received much attention and considerable aid from members of the Society; and the papers read by Mr. Blanchard and Mr. Spiller during the past year may be regarded amongst the most important contributions of the Society to the progress of this branch of our art. The optics of photography have received great impulse from the contributions of the members, and the papers of the late M. Clandet and of M. Dallmeyer, and from the discussions arising from their papers read during the year. Dry-plate photography, amongst the many contributions which have, during the past year, aided in securing its practical perfection, has received an especial impulse from the paper of Mr. England, who, in his communication, described a process which has for the first time proved as commercially available as the wet process for the practice of professional photography.

Without entering into further details upon the numerous and important steps in advance which have been secured in the art, the Council submits a list of communications which have been received at various meetings of the members, and at the same time direct attention to the fact that they are more numerous and important than usual, no meeting of the Society having been held at which one or more interesting papers was not read:—

Dr. Wright, on the Medical Uses of Photography.

Mr. A. Clandet, on a Photographie Unity of Measure, for calculating any enlargement or reduction of photographic reproductions, and all respective focal distances and distances of objects.

Mr. Holwell, of Bermuda, on Mr. Clandet's Invention for the Distribution of Focals.

Mr. A. K. Sparke, of Plymouth, on a New Developer.

Mr. Mouckhouse, on a Water Agitator for washing photographic prints.

Mr. Jabez Hughes, on Papers—How to write them, and What to write about.

Mr. W. T. Bovey, on Printing on Canvas and Wood Blocks.

Mr. W. England, on a Modification of the Collodio-Albumen Process, requiring but one sensitizing bath.

Mr. A. Clandet, on the Optics of Photography—on a Self-acting Focus Equalizer, or the means of producing the differential movements of the two lenses of a photographic optical combination, which is capable, during the exposure, of bringing consecutively all the planes of a solid figure into focus, without altering the size of the various images superposed.

Mr. V. Blanchard, on the Best Means of rendering Silver Prints Permanent.

Mr. Dunmore, on Bromo-Rice Paper.

Mr. J. H. Dallmeyer, on the Cause of the Central Spot or "Flare" in Photographic Lenses; and on a New Form of Wide-angle Rectilinear Lens entirely free from this defect.

Mr. Jabez Hughes, How is the Status of Professional Photography to be raised?

Mr. J. Spiller, Researches on the Hyposulphites and other Fixing Agents—Part I.

The following interesting objects have been exhibited during the session:—

Dr. Loewo, Specimens of various Solutions for Printing on silk, linen, wood, leather, ivory, and other substances; also prepared paper and photographs on various materials.

Mr. N. K. Cherrill, Photographs printed in Carbon.

Mr. Good, a Frame for Touching Negatives.

Mr. Griggs, a Photo-block.

Mr. J. R. Johnson, a Multiplying Camera.

The Council has pleasure in stating that arrangements have been made for the future management of the Society, which, without in any degree crippling its efficiency, will very considerably further reduce its annual expenditure.

The Council has especial pleasure in mentioning, amongst the most important means of reducing the expenditure of the Society, a voluntary tender on the part of their Secretary to resign the amount of salary he has hitherto received for discharging the duties of that office, and of undertaking, for such time as may be necessary, the position of Honorary Secretary. The Council, in accepting the offer of Dr. Diamond, feels

assured that the Society will join with it in tendering their cordial thanks for the liberal spirit in which he has undertaken onerous and important duties on behalf of the Society without any charge upon its funds.

The Council further has pleasure in referring to a source of reduced expenditure and increased comfort, which is found in the change in the place of meeting from the Library of King's College to the Gallery of the Architectural Union in Conduit Street. In opening its session at the commencement of the present winter, the Society, in accordance with an announcement at the termination of last session, had arranged to hold an exhibition meeting to which photographers generally, as well as its members, were invited to contribute illustrations of the progress made during the year in the various departments of the art. On application to the authorities of King's College for the use of their meeting-room a few hours earlier than usual, in order duly to display the contributions which had been invited, it was found that no departure from the usual routine as regards the use of the room would be granted; and the Council were compelled to look elsewhere for rooms in which the exhibition meeting could be held. This accommodation was granted with much courtesy and on exceedingly moderate terms at the Gallery in Conduit Street, at which the meetings are now held. The greatly extended accommodation, and the comfort and convenience which attended the proceedings of the first evening induced the Council to enter into negotiations for the occupation in future, for meetings and other purposes, of the Gallery, in which the opening of the session was inaugurated; and they have pleasure in congratulating the members on the success of these negotiations, which have issued in a change in every way advantageous, at a cost little exceeding half the amount they had hitherto paid for rent.

The Council has already referred to the very great success of the exhibition meeting held on the 12th of November last. The response made to the invitation of the Society was far beyond anticipation, and a very large number of photographs of much excellence were forwarded for exhibition. Impressed with the importance of giving, if possible, an extended opportunity to photographers and the public to examine the choice display of pictures hung in the gallery, the Council made arrangements to continue the exhibition for a week longer, during which time the rooms were opened to the public free of charge, and a considerable number, probably exceeding 2,000 persons, availed themselves of the opportunity of visiting an exhibition of photographs which was, in many respects, unsurpassed in interest by any which had been held for many years. The success which has attended this exhibition has induced the Council to determine on a repetition of the experiment in future years, when it is probable that increased publicity and more perfectly organized arrangements will secure a still higher success and more complete satisfaction. The Council cannot leave this subject without expressing their gratification that the great impulse which public exhibitions afford to the progress of the art may be secured to photographers by arrangements similar to those of November last, without the heavy tax upon the funds of the Society which, continued during many years, so crippled its resources, and have acted so prejudicially on its financial position.

The Council has to announce with deep regret the loss it has sustained during the year by the death of two of its most esteemed members, Mr. Claudet and Mr. Thurston Thompson, both of whom had maintained to the time of their death a warm attachment to the Society, and an active interest in its welfare and progress. The Council had received considerable aid from the able assistance of these gentlemen for many years; and it and the Society sustained a deep loss by their lamented death.

In conclusion, the Council would impress upon members that the continued prosperity and progress of the Society are dependent on the co-operation of all its parts, upon the active discharge by individual members of personal duties, by regularity of attendance, by contribution of papers, by the exhibition of objects of interest, either as means of production or in the shape of perfection of results, by aiding in the discussion of all matter pertaining to the art brought before the Society, and upon the general activity of members in extending the influence of the Society, as much as upon the action of its Council and its executive officers, who are largely strengthened in their efforts by the tone of the Society generally, and a consciousness that every member is contributing, each in his own sphere, to the furtherance of the interest of the Society and the beautiful art which the Society was founded to promote.

## Proceedings of Societies.

### THE SOUTH LONDON PHOTOGRAPHIC SOCIETY.

The usual Monthly Meeting was held in the City of London College, on the evening of Thursday, February 13th, Mr. SEBASTIAN DAVIS in the chair.

The minutes of a preceding meeting having been read and confirmed, Mr. J. F. B. Hassett was elected a member of the Society.

Mr. J. T. TAYLOR then read a paper on the "Oxyhydrogen Light, and Means of Avoiding Explosions," illustrating by means of diagrams on a blackboard the working of a valve he had used by which escape and mixture of the gases was rendered impossible. We regret that the extreme pressure on our space compels us to defer the publication of this paper until next week.

After some conversation on the excellence of the plan suggested, and a vote of thanks,

Mr. SAMUEL FRY read a paper entitled "Omnium Gatherum," consisting of observations on a variety of photographic topics (see p. 92).

Mr. WHARTON SIMPSON said it was quite refreshing to hear a paper on photography containing so many decided opinions and sweeping assertions, especially as it had concluded with a text, or motto, which he felt sure must have been kept in view in preparing the paper: he referred to the remark that where knowledge ended, dogmatism began. Remembering this as the motto of Mr. Fry's paper, they might fairly assume that the strong opinions expressed were based upon very careful examination of the subject. With the greater part of Mr. Fry's excellent paper he cordially coincided; but still, he thought, one or two points were open to further consideration. If the collodion, and resins, or gums which Mr. Fry had denounced as worthless for preserving prints because of their own perishable nature really were so liable to decomposition, their negatives were in a perilous condition, being formed of the one and protected by the other. He quite agreed with Mr. Fry that it was more important to expel the enemy than to imprison him; but having taken pains to get rid of him by care in the production of the print, he thought that some of these protective substances might be useful in keeping him out of the finished print. Varnish gave a vulgar surface which persons of taste in art could rarely tolerate; but he still thought that collodion applied as suggested by Mr. Blanchard, whilst it gave no vulgar gloss, ought to act as a protection to the print. As to the value of wax, he endorsed every word which Mr. Fry had said. Regarding carbon printing, many reasons might be given for the limited extent to which it had as yet been taken up. Where it had been worked on a large scale it was found easy, certain, and economical. Braun, of Dornach, was at the present time producing 500 prints a day, and was making arrangements to produce 1,500 daily. He was so convinced of their superiority that he had burnt his stock of silver prints. In his own experience, which was not large, but extended, perhaps, to the production of a hundred prints, he found that guessing the exposure was as easy and certain as guessing the exposure of dry plates. As to stability, the material composing a carbon print was very similar to the sizing on highly glazed writing-paper, consisting in both cases of gelatin rendered insoluble by chemical agency; and they might, he thought, as legitimately expect one to perish or decompose as the other.

Mr. BLANCHARD said that he could not help feeling that the position he had taken some time ago was the right one. Assuming that all had been done to render a print safe, it still consisted of silver and gold, and, as Mr. Spiller had shown, chiefly silver. This would, unless protected from atmospheric action, be liable to change, especially in sunlight, the silver remaining in the whites being manifestly liable to become yellow, as vignette pictures invariably showed. Hence the necessity of protective substances; and he believed that collodion was best. It was difficult to apply, he would admit, especially on account of the action of the ether. He now himself always applied wax, and had done for some time. As to any one putting prints into a tank, and after leaving them a few hours removing them as washed, he could not have believed it possible. In his own establishment they were always tested, after washing, with iodide of starch; but, notwithstanding every care, some turned yellow.

Mr. WERGE stated that he had some prints taken between 1855 and 1860 which remained perfectly good. They were washed in repeated changes of hot water, gradually increasing the heat to nearly boiling point, and then gradually changed down again to cold water. He had generally finished fixing by the use of a fresh strong hypo bath after the use of hypo and gold. He believed much of fading was due to the fixing and washing being left to ignorant people and boys.

Mr. HART referred to prints sticking together in the fixing and washing as a cause of imperfect treatment.

Mr. BLANCHARD said that a custom used to prevail of giving long immersion in weak hypo. He now used very strong hypo, and only immersed five minutes.

Mr. HASSETT referred to the importance of individual treatment of each print in fixing and washing. In toning we were compelled to do this, or we should have stains.

After some further conversation on the subject, in which Mr. Foxlee, Mr. Hart, Mr. Henderson, Mr. Blanchard, Mr. Fry, Mr. Simpson, and the Chairman took part, a vote of thanks to Mr. Fry terminated the proceedings.

## Talk in the Studio.

**MOUNTS FOR CARDS AND CABINET PORTRAITS.**—We have recently received from Marion and Co. some examples of the cards they provide for mounting cabinet and card portraits, with a variety of designs and degree of excellence in printing them rarely met with. Every form of ornamental border and inscription for the backs of the cards are here found, and some of the cabinet mounts, with a neat line round the face of the card, to serve as a finish for the picture. Our own taste runs in favour of the quietest and neatest of the designs, of which there are many; but every phase of taste may here find something satisfactory.

**NEW USE FOR A COLLODION BOTTLE.**—A correspondent sends a suggestion which he thinks may be of service to his brother photographers. After describing a summer-house in a garden in which himself and family were in the habit of ruralizing on Sundays, he found one morning, when he arrived as the *avant courier*, that the matches were so damp that none would light, and, as it was Sunday morning, there was little chance of breakfast. The sun was shining, and an empty collodion bottle was at hand, the bottom of which seemed convex. It was quickly broken, and served as a lens or burning-glass to concentrate the sun's rays and light the damp matches.

## To Correspondents.

**NORTHERN LIGHT.**—The lens which you describe has evidently a chemical focus; that is, the chemical focus and the visual focus do not coincide. To get a sharp image on your sensitive plate, the visual focus must be on a different plane to the ground glass. Focus the image sharp, on a point a little behind the face, say the ear or the back part of the head; or focus sharp as usual, and then give the rack a turn so as to throw the focus back a little, and try the result. 2. The plan you propose will doubtless illuminate your background more evenly; but can you not move the background so as to bring it within the range of such illumination as you now have? 3. See a leader in our present number.

**ENQUIRER.**—We have tested the cards forwarded for hyposulphite of soda. Nos. 1 and 3 are quite free from it; but No. 2 gives undoubted indications of its presence, and should be rejected.

**E. G. H. X.**—The specimens you forward have many excellent qualities. The tone and printing are very good, and the lighting is also good. The shadow cast by the curtain on the background has a very good effect. Your background is somewhat too dark for vignette portraits, and renders the gradation to the white margin somewhat abrupt. Study the articles on Composition at present appearing in our pages, and you will improve in that respect.

**A.**—You state the facts of the ease as regards the requirements in producing photolithographs with half-tone very fairly; but you do not include quite all the difficulties. The first requirement is to get the image on the stone with photographic gradation transformed into stipple; but this is not quite all. It must be in such a gradation as will not readily clog and fill up in printings, which a very

fine grain is apt to do; at the same time, it must be in a grain not too coarse to do justice to the photograph.

**J. ARKWRIGHT.**—The studio of which you send a model is, in all respects, very excellent, both in proportion and dimensions. With such an expanse of high side-light it is probable that you will generally find it desirable to have the skylight covered with blinds; or, possibly, to have a portion or the whole of it stippled in imitation of ground glass. This can be done, however, after trial.

**BETA.**—We believe that a thoroughly skilled workman in colouring photographs in oil may obtain plenty of commissions; but we have no connection with commercial photography which will enable us to assist in procuring such commissions. There are two modes of securing a connection: one consists in direct personal communication with first-class photographers, and the other in announcing your wish in our advertising columns. We shall have pleasure in examining a specimen of your work.

**S. W. B. L.**—The difficulty arising from facing the south is that whenever the sun shines it will render the use of blinds necessary, and the inconstancy of the light necessarily involves additional trouble; but with care and skill, and constant watchfulness of changing light, good results may be obtained in a glass room facing south.

**D. S.**—For landscape work the wide-angle single lens of the maker you name will answer better than the others, and for stereo work the patent lens of the same maker. The tent you name will answer well. The cards have some very good qualities. The vignette is a little too low down on the plate.

**W. J. A. G.**—You will find various articles on Sayce and Bolton's collodio-bromide process in the last two or three volumes. Mr. Sayce gives full particulars on p. 305 of our Ninth Volume, and an abstract appears in our YEAR-BOOK for 1866. We cannot tell you the extent to which the process is used. 2. We do not know the nature or composition of Cleaver's Photographic Soap. 3. *Punch's* proposed tax on photographs would not affect amateurs. 4. You get a certain amount of the effect of the gelatino-iron developer by adding gelatine to the developer. See the chapter on the subject in our last YEAR-BOOK. 5. As a rule, about 4 or 5 ounces of water added to 1 grain of gold will answer well, whatever other salt may be added.

**MORPHINE.**—As plates prepared by the morphine process are very sensitive, the strong light of a gas flame will be dangerous if too near the plate. Drying in front of the fire would also be dangerous. A solution of wax in benzole is good for edging the plates.

**H. S.**—There is no work devoted to enlargements. It is difficult to state which is the best method of enlarging, as various methods each have their specific advantages for especial purposes. You will find detailed instructions for transferring the film in our article on camera enlarging at the end of last volume, and also in our last YEAR-BOOK. We tried the bath, and did not find any tendency to the streaks described. We intend to try it again, however, with several samples of collodion.

**MINIATURE.**—The best method of printing on ivory with which we have had practical experience consists in the use of a powdery collodion saturated with nitrate of uranium, and containing 4 grains of nitrate of silver to each ounce. Print deep, and tone and fix as usual. The collodion film may be removed by means of ether, and the image will be found on the ivory underneath.

**STEWART.**—The facts you describe are perplexing. The paper presents no indication of decomposition or defect of any kind; but, from your account of the circumstances, it appears difficult to assign the defects in the print to any other cause. If it be really the result of a change or decomposition in the paper, we fear that there is no cure; but we should like to examine a little further before pronouncing the paper in fault. Send us a piece excited on your bath, and we will also excite that sent, and test both samples.

**W. G. G.**—Your letter of February 4th, having been put aside in order that the soluble cotton might be tested before giving an opinion upon it, was overlooked until now. The pyroxiline seems to be very excellent; we find that it dissolves readily and perfectly at the rate of 6 grains to the ounce, and would dissolve in much larger proportion; but that is about the right quantity for use. The film is structureless and quite transparent, and the collodion will, we doubt not, work well.

**IGNORAMUS.**—There are no curtains or blinds to the top-light, the canopy over the head of the sitter serving instead. The side curtains are of blue calico. 2. Yes; the plan you propose is similar. 3. Paste made of white wax dissolved in an essential oil; it is applied as wax is employed for polishing furniture. We shall have more to say on this subject shortly.

**A REPRODUCTION** from an oil painting of an ox has reached us without any note of reference to it. We shall be glad to hear from the correspondent who sends it.

An Article on the Financial History and Present Position of the Photographic Society, and several other articles in print, are compelled to stand over until our next.

Several Correspondents in our next.

## THE PHOTOGRAPHIC SOCIETY OF LONDON.

At the annual meeting of the Photographic Society, held on the 11th instant, Mr. Glaisher expressed a conviction that the Society had reached a turning-point in its history, and, in one sentence, indicated the cause of the difference between its present and its former financial position. It was, he said, at one time *fashionable* to patronise photography and support the Society; the fashion had passed away, and the Society was now, and had been for some time, dependent simply upon ordinary resources. Nevertheless, many of the expenses, originated when funds were exceedingly ample, had been continued after its sources had been diminished. After a due examination of all the facts, and a preparation to meet the necessities of the case, he believed the Society to be in a healthy and promising position.

We have no hesitation whatever in expressing our conviction that the Society is in a healthy and promising condition. We say this advisedly after a careful examination of the facts and a consideration of the desponding views of some of the friends of the Society, and the evil reports of some who are much otherwise than friendly in their wishes as well as in their prognostications. There are, in most communities, some malcontents who, from personal pique or for the purpose of gaining personal ends, are ever ready to sow the seeds of disaffection; and there are also—fortunately, probably, for the progress of improvement—generally some honest reformers who readily believe in the existence of grievances, and who mean well in their denunciation of real or fancied abuses. To either class the discovery of a declining financial position presents obvious matter for alarm or denunciation. Nevertheless, we see little ground for anxiety in the admitted declension in the funds of the Photographic Society. We think that a brief glance at the facts will justify the position we have assumed.

We may first premise that a prosperous financial position would very inadequately represent success in a society established to promote the welfare of an art-science like photography. It might rather suggest lack of activity, or apathy in the discharge of duties involving expenditure of the funds existing for a specific purpose. Let us, however, briefly glance at the financial history of the Society.

At the end of the first year of the Society's existence the amount received from members was nearly £650; but this included not only subscriptions, but entrance-fees and the compositions for life-membership, more than half that

sum, therefore, arising from sources which could not occur again. For a few years, however, the income, from subscriptions, from profits upon exhibitions, and from profits upon the Journal, continued to be in excess of the expenditure until, in 1857, the Society possessed over £1,000 of funded property. Then began a change, and the expenditure exceeded the receipts, a state of things which has, we believe, continued ever since. In regard to the profits to which we have referred, it should be observed that, although the journal was not established as a commercial speculation, but to supply a means of inter-communication between photographers and of promulgating information conducive to the advancement of the art, being alone in the field, or nearly so, it soon became in the nature of things a source of profit; and, equally naturally, since the progress of photographic journalism as a private enterprise, it has ceased to be a source of profit, as the monthly organ of a society could scarcely be supposed to compete with financial success against weekly journals conducted with commercial energy. The exhibitions, during the novelty of the art, were also sources of profit, the receipts on some occasions having reached nearly £350; whilst in later years, when the attractions of novelty and the glamour of fashion wore off, the receipts became almost *nil*, whilst the expenses were as heavy, or nearly so, as before.

But what became of the funded property? may be asked. Was it wasted, or was it spent in promoting the progress of the art and the welfare of its devotees? We think that it can easily be shown that it has been expended in the main with a view to the promotion of the art and for the benefit of the members: whether on all occasions with judgment or not is another question; but any doubtful judgment which has been manifest belongs to years gone by, and is in nowise attributable to the successive councils which have been in office for at least the last half-dozen years. The heaviest drain upon the funds was occasioned by an attempt to provide a permanent home for the Society, where reading rooms duly furnished with photographic literature, laboratory, glass room, &c., for experiment, the other paraphernalia of a photographic institution, and a constant attendant should always be at the service of its members. The premises taken in Coventry Street for this purpose cost the Society, for alterations, furniture, fittings, &c., about £700; the whole of which, or very nearly, was eventually a total loss to the Society, besides the heavy loss involved in a two years' tenancy at £300 a-year. The intention was doubtless a worthy one; but the project was not successful, and had, after two years' trial, to be abandoned.

Other sources of loss followed: some, doubtless, from expenditure of value to the art; others of a less satisfactory nature. Foremost amongst the extra sources of justifi-

liable expense was the aid given to the committee for ascertaining the causes of instability in prints. Next followed a series of exhibitions of undoubted service to the art, but involving heavy loss. Instead of a profit, as in previous years, the exhibitions of the years 1858-59 involved a loss of over £112, and the expenses of that year were nearly £60 in excess of receipts. Exhibitions of other years were also losses, and we find each year's expenses in excess of receipts, the expenses of the year 1860-61 being £354 in excess of income. Amongst the expenses of a less useful character may be mentioned upwards of £100 for the costs of the Collodion Committee, the report of which gave so little satisfaction; about £100 of costs were incurred in defending the Society's copyright in the title of its Journal, an expense inevitable under the circumstances, however little satisfactory in its nature; and some other trivial matters.

All, or the chief of, these heavy expenses, which absorbed its accumulated funds, belong, however, to the first decade of the Society's history, and although its disbursements have for years past exceeded the income, they have done so in gradually diminished ratio, and have been—we think it cannot be doubted—for legitimate aids to the progress of the art.

How, then, it may be asked, can it be affirmed that the Society is in a healthy or promising condition? The answer is simple and straightforward. It is because, by the exercise of energy and judgment on the part of the Council, and the aid of earnest members, the expenses have been diminished without crippling the activity and usefulness of the Society. The year just concluded shows a less deficit than has existed for years,\* whilst the vitality of the Society has been greater. There were more members elected last year than have been, we believe, for several preceding years; there were more papers read, and a better, although less costly, exhibition was held, to the great satisfaction of photographers generally.

Thus much for the past year. But the Society commences a new year under still more promising auspices. The Secretary, Dr. Diamond, has, with a liberality which those who know him know to be characteristic of him, resolved to resign his annual remuneration, and to continue his duties without any charge on the funds of the Society. With increased accommodation and comfort at the new rooms in Conduit Street there is a considerably reduced cost for rent and refreshment. These and some other sources of reduction in expenses will entirely change the financial position of the Society, and we look forward confidently to the next annual meeting for the novelty of a balance in hand instead of the report of a deficit. We believe that there is increased energy and interest also amongst the members. The year began well; at its first meeting, besides anniversary proceedings, a most valuable paper was read by Mr. Johnson, an interesting and illustrated note on experiments in lighting was read by Mr. Dunmore, and a most successful and instructive demonstration of enlargement made by Mr. Solomon. Two papers are promised already for March, and one for April. These circumstances, we are satisfied, point to a healthy present condition, and give promise of renewed vitality and prolonged usefulness in the oldest and most representative of existing photographic societies.

\* The deficit for the year appears from the published accounts to be between £40 and £50. The expenses of the year appear to stand thus:—

Nett cost to the members of the Journal	£130	8	10
Secretary's salary	75	0	0
Rent and refreshments at King's College, including an unexpected demand of payment in lieu of notice	51	14	3
	257	3	1
Ordinary income of the year	214	15	0
Deficit	£42	8	1

A trifle more, it is probable, should be added to the expenditure for petty cash, &c.; against which, however, may be reckoned the year's stock of Journals on hand, many of which will probably be sold in volumes.

## PHOTOGRAPHY AND DISEASE.

WE have on repeated occasions cautioned photographers against the careless use of cyanide of potassium and other dangerous poisons used in photography, the absorption of which through the unbroken skin was dangerously possible. We have also expressed a conviction that, conducted with ordinary care, there was nothing in the ordinary operations of photography which should have a detrimental effect on health. By ordinary care we mean the use of reasonably well-ventilated operating rooms; the avoidance of contact between the skin and poisonous solutions; and a similar avoidance of contact between the lungs and injurious vapours: all these are possible conditions, and ought imperatively to be secured. We have now to call attention, either to some new possible forms of injury to which photographers are liable, or, on the other hand, to secure some testimony to the effect that two of our correspondents who are suffering are under some delusion as to the origin of their symptoms.

We have received this week two letters from correspondents who seek advice from ourselves, or some of our medical readers, as to the cause and remedy of sufferings which they attribute to photography. The first is brief and indefinite, briefly and generally stating symptoms, and asking if they are known to be common to photographers. It runs as follows:—

"A SUFFERER would like to know if the Editor has had under his notice persons who have suffered from the effects of collodion, acids, nitrate of silver (cyanide sufferer does not use). The symptoms are as follows:—Attacks of biliousness; inaction of the liver, with a great deal of wind and spasms in the stomach; very acid stomach, and general indigestion. What would be the best mode to guard against these ailments? My life has been a misery to me for the last nine years, ever since I began photography; but as I like it I don't like to give it up. I have consulted most of the best doctors, and they don't seem to hit on the right thing for relieving me."

The symptoms described are, we fear, too common outside of photography: they may arise from various causes, and, so far as we can judge, they are not in anywise fairly traceable to photography or the materials used in its practice. Any occupation which overtaxes the nervous system, induces sedentary habits, and especially which occasions irregularity in taking food, may induce in a delicate constitution all the symptoms mentioned, quite apart from photography. The duties of a professional portraitist do not necessarily involve sedentary habits: the hours of work are not excessively long, but permit plenty of time for exercise, both before commencing and after concluding the day's work; but, too often, that exercise is neglected. The duties do, it is true, at times keep the nervous system on the strain, and they also not unfrequently involve irregularity in eating, a dangerous habit for persons of sedentary habits or weak digestion, which should be avoided. If the dark room be ill-ventilated, the vapour of ether and alcohol will also have an injurious effect; but this and similar obviously injurious conditions will, as a matter of common sense, be avoided by persons who suffer from imperfect health.

The next letter is much more specific as to the alleged source of injury, but scarcely so probable as specific. An occasional practical correspondent writes:—

"I have written to you several times before on practical matters; but this time I am sorry to say that it is upon a very different subject: a subject which, I think, ought to be made known amongst photographers, as my case appears to be different from any that I have ever read in the *News*. Still, there may have been such cases, although not published; and if, through the medium of the *News*, I could hear of a case similar to my own, and the way the case has been treated, I should be glad, as it might be some aid and comfort to me.

"Since last autumn I have been suffering very much from

illness at different times, although able to keep about, being much better some days than others, but all the time very weak and unable to attend to business (I mean the operating part of it).

"I have had strong suspicions that the chemicals have affected me for a long time; but as those used in the dark room are generally suspected and often condemned, I have always guarded myself against their action (I mean such as collodion, cyanide, &c.) But the real cause of my illness is nothing but the washing water in which the prints are immersed before toning, or rather the cause is the chloride of silver there formed. My blood appears thoroughly contaminated with it, and causes my limbs to be as though they were paralyzed, and often almost helpless. This is all caused through washing the silver off the prints with my hands before toning. I do not ever remember seeing that the washing water was ever dangerous before mentioned in your News, although I have the News from the commencement; so I would strongly advise all photographers to be guarded against the great danger there is in putting their hands into the washing water before toning. I can assure you that the feelings that it produces are anything but agreeable, and appear most difficult to get rid of.

"I have had ten years' hard work at it, and always was very healthy and strong; but now I am neither. I am now under a clever doctor, and he tells me had I let the case go on a very little longer I should have been quite hopeless, as my system is strongly impregnated with chloride of silver. If you have heard of any such cases before, and know of any remedy, I should feel glad if you would let me know. I am, dear sir, yours most respectfully, B. B."

This case, we must confess, somewhat puzzles us; and whilst we hesitate to doubt a statement so definitely made on the authority of our correspondent's medical man, we nevertheless feel considerable hesitation in the acceptance of the explanation of the symptoms given. Poisons are undoubtedly absorbed through the skin; but as a rule they must be in solution to admit of such absorption, and chloride of silver being insoluble, it is not in a condition for ready absorption by mere contact with unbroken cuticle. What effect would be produced on the system by chloride of silver once in the system it is difficult to say, as there are no records in the text-books of such a thing having taken place. It might be assumed to be comparatively inert, inasmuch as when nitrate of silver, which has a poisonous action, has been swallowed, common salt has been administered to convert it into chloride of silver, which is vomited and the poisonous action arrested.

The washing waters contain, of course, some nitrate of silver, and this may be absorbed and act injuriously. The symptoms of silver on the system, although rare, are tolerably well marked, producing generally discoloration of the skin. What is the effect on the general health we cannot state. Chloride of gold, as our readers have already had pointed out to them, may be absorbed by the skin and act injuriously. Sulphate of iron may be absorbed by the skin and produce symptoms analogous to local paralysis; but, as we often urged, none of these things need to be handled, and ought not to come into injurious contact with the skin.

As to the possibility of injury from the action of chloride of silver formed in the washing water, we cannot, of course, speak with certainty, and there can be no harm in using caution, as no photographic operation renders contact with chloride of silver necessary. We scarcely think it probable that the injury has arisen from the cause mentioned, but shall be glad to have the opinion of any of our readers whose studies or experience may enable them to throw any light on the subject.

#### MODIFIED CARBON TISSUE.

M. DESPAQUIS brought before the recent meeting of the French Photographic Society some examples of a slight modification of the carbon process, for which he claimed

certain special advantages. His description of the details of working is scarcely so clear as might be wished. The material used for the print he styles *papier-collodion-cuir*, or a paper of leather collodion. This appears to be the material described some time ago by Dr. Vogel in our columns as an agent superior to gelatine for transferring negatives, and used for some time by Mr. Woodbury in his photo-relief process. It consists of collodion to which castor oil has been added, and in some cases a little "driers."

M. Despaquis stated that, owing to the smooth oily nature of the collodion film, the adherence of the sensitive layer of bichromate and gelatine was so perfect that wherever the latter had been but very slightly acted upon by the light, a very thin insoluble film remained, which, of course, furnished half-tones of the most delicate description; this was not the case if the gelatine was supported by paper, mica, or a film of ordinary collodion, for the operation of washing, especially if the temperature of the water exceeds 60° C., has the effect of removing these finer gradations of tone. If desired, the surface might be rendered transparent or dull, and tinted to any colour. To produce a dull opaline surface the collodion paper is plunged into warm water prior to its perfect desiccation, the warmer the water the more dull being the appearance of the surface. The sensitive mixture is applied by allowing the prepared collodion paper to float on the same for a short time, the bichromate and gelatine being kept in a tepid condition during the process, and employed of a somewhat thicker consistence than ordinarily, in order to make it adhere more tenaciously. It is composed of—

Water	...	...	...	80 grammes
Liquid Indian ink	...	...	20	"
Gelatine	...	...	15	"
Bichromate of ammonia	...	...	2	"

#### THE USE OF CLOUDS AS BACKGROUNDS IN PORTRAITURE.

BY LUX GRAPHICUS.

THERE has long been in the world an aphorism that everything in Nature is beautiful. Collectively this is true, and so it is individually, so far as the adaptability and fitness of the object to its proper use are concerned; but there are many things which are truly beautiful in themselves, and in their natural uses, which cease to be so when they are pressed into services for which they are not intended by the great Creator of the universe. For example, what can be more beautiful than that compound modification of cloud forms commonly called a "mackerel sky," which is sometimes seen on a summer evening? What can be more lovely, or more admirably adapted to the purposes of reflecting and conducting the last flickering rays of the setting sun into the very zenith, filling half the visible heavens with a fretwork of gorgeous crimson, reflecting a warm, mysterious light on everything below, and filling the mind with wonder and admiration at the marvellous beauties which the heavens are showing? Yet, can anything be more unsuitable for forming the background to a portrait, where everything should be subdued, secondary, and subservient to the features of the individual represented—where everything should be lower in tone than the light on the face, where neither colour nor light should be introduced that would tend to distract the attention of the observer—where neither accessory nor effect should appear that does not help to concentrate the mind on the grand object of the picture—the likeness? Still, how often do we see a photographic portrait stuck against a sky as spotty, flickering, and unsuitable as the one just described! How seriously are the importance and brilliancy of the head interfered with by the introduction of such an unsuitable background! How often is the interest of the spectator divided between the portrait and the "overdone" sky, so elaborately got up by the injudicious background painter! Such backgrounds

are all out of place, and ought to be abandoned—expelled from every studio.

As the photographer does not possess the advantages of the painter, to produce his effects by contrast of colour, it behoves him to be much more particular in his treatment of light and shade; but most particularly in his choice of a background that will most harmonize with the dress, spirit, style and condition in life of his sitter. It is always possible for a member of any class of the community to be surrounded or relieved by a plain, quiet background; but it is not possible, in nine cases out of ten, for some individuals who sit for their portraits ever to be dwellers in marble halls, loungers in the most gorgeous conservatories, or strollers in such delightful gardens. In addition to the unfitness of such scenes to the character and every-day life of the sitter, they are the most unsuitable for pictorial effect that can possibly be employed. For, instead of directing attention to the principal object, they disturb the mind and set it wandering all over the picture, and interfere most seriously with that quiet contemplation of the features which is so necessary to enable the beholder to discover all the characteristic points in the portrait. When the likeness is a very bad one this may be advantageous, on the principle of putting an ornamental border round a bad picture with the view of distracting the attention of the observer, and preventing the eye from resting long enough on any one spot to discover the defects.

When clouds are introduced as backgrounds to portraits they should not be of that small, flickering character previously alluded to, but broad, dark, and "massy," so as to impart by contrast more strength of light to the head; and the lighter parts of the clouds should be judiciously placed, either above or below the head, so as to carry the light into other parts of the picture, and prevent the strongly lighted head appearing a spot. The best examples of that character will be found in the engraved portraits by Reynolds, Lawrence, Gainsborough, and others, many of which are easily obtained at the old print shops; some have appeared in the *Art Journal*.

As guides for introducing cloud effects, accessories, and landscape bits into the backgrounds of cartes-de-visite and cabinet pictures, no better examples can be cited than those exquisite little figure subjects by R. Westall, R.A., illustrating Sharpe's Editions of the Old Poets. The engravings are about the size of cartes-de-visite, and are in themselves beautiful examples of composition, light and shade, and appropriateness of accessory to the condition and situation of the figures; affording invaluable suggestions to the photographer in the arrangement of his sitter or groups, and in the choice of suitable accessories and backgrounds. Such examples are easily obtained. Almost any old book-stall in London possesses one or more of those works, and each little volume contains at least half-a-dozen of these exquisite little gems of art.

Looking at those beautiful photographic cartes-de-visite by Mr. Edge, I am very strongly impressed with the idea that they were suggested by some such artistic little pictures as Westall's Illustrations of the Poets. They are really charming little photographs, and show most admirably how much the interest and artistic merit of a photograph can be enhanced by the skilful and judicious introduction of a suitable background. I may as well observe, *en passant*, that I have examined these pictures very carefully, and have come to the conclusion that the effects are not produced by means of any of the ingeniously contrived appliances for poly-printing, recently invented and suggested, but that the effects are produced simply by double-printing, manipulated with consummate care and judgment,—the figure or figures being produced on a plain or graduated middle tint background in one negative, and the landscape effect printed on from another negative after the first print has been taken out of the printing frame; the figures protected by a mask nicely adjusted. My impressions on this subject are strengthened almost to conviction when I look

at one of Mr. Edge's photographs, in particular a group of two ladies, the sitting figure sketching. In this picture the lower part of the added landscape—trees—being darker than the normal tint of the ground, shows a line round the black dress of the lady, as if the mask had overlapped it just a hair's breadth during the process of secondary printing. Be that as it may, they are lovely little pictures, and afford ample evidence of what may be done by skill and taste to vary the modes of treating photography more artistically, by introducing natural scenery sufficiently subdued to harmonize with the portrait or group; and by similar means, backgrounds of clouds and interiors may be added to a plain photograph, which would enrich its pictorial effect, and enable the photographer to impart to his work a greater interest and beauty, and at the same time be made the means of giving apparent occupation to his sitter. This mode of treatment would enable him, in a great measure, to carry out the practice of nearly all the most celebrated portrait painters, viz., that of considering the form, light, shade, and character of the background *after* the portrait was finished, by adapting the light, shade, and composition of his background to the pose and condition of life of his sitter.

I shall now conclude my remarks with a quotation from Du Fresnoy's "Art of Painting," bearing directly on my subject and that of light and shade:—

"Permit not two conspicuous lights to shine  
With rival radiance in the same design;  
But yield to one alone the power to blaze,  
And spread th' extensive vigour of its rays;  
There where the noblest figures are displayed,  
Thence gild the distant parts and lessening tale:  
As fade the beams which Phœbus from the east  
Flings vivid forth to light the distant West,  
Gradual those vivid beams forget to shine,  
So gradual let thy pictured lights decline."

#### DISTILLED WATER IN PHOTOGRAPHY.

BY NELSON K. CHERILL.

HAVING been much occupied of late with matters of more importance, I have not before found time to answer the remarks made by your correspondent, R. H. P., on my former paper "Against the Use of Distilled Water."

It appears to me to be more a matter of individual experience than of actual scientific investigation, whether or no distilled water is necessary in ordinary photographic operations; one thing seems pretty certain, however, viz., your correspondent is a very thorough believer in distilled water, and, moreover, he goes the right way about to get it by using his own still, and not trusting to the stuff they usually sell at the chemists for distilled water. Whether distilled water be required or no, I would say, avoid the supply unless you know where it comes from. Of course pure distilled water is to be bought, but there is a great amount of very impure water sold under the name "distilled." Much that is sold under this name is not prepared in proper stills made for the purpose, but is merely "condensed water" (as it is technically called) from steam-engines and boilers where no sort of pains are taken to keep it free from any impurity or contamination to which it is liable. Boilers are often fitted with "grease pumps," by which a little melted tallow or other grease is forced into the boiler when in action, to prevent its priming; the steam from this greasy water is condensed by jets of impure water from any source which may be at hand (all pumped up through greasy pump barrels and valves), and the delightful mixture so formed in the internal economy of the engine trickles out at a small pipe, and is often put up in casks and sent to London as "distilled water."

Then, again, I have often had distilled water (?) sold me which had quite a delicious perfume. No doubt it had been kept in a carboy or bottle which had not been properly washed out since last it held rose water or some such scent; and, as a rule, when I kept a supply of distilled water, it "went bad" in various ways, often throwing down quantities

of matter of different forms and colours, and sometimes even smelling. So, with all these things against it, I thought that distilled water was a delusion, and gave it up.

I have certainly succeeded well without distilled water, and I should much like to know if your correspondent has done better with it than I have without it, only I do not see exactly how such a comparison can very well be instituted.

It seems, also, that on one point your correspondent has slightly misapprehended my letter. He says, "It is like straining at a gnat and swallowing a camel," to ask and pay for pure silver and other chemicals, and then to mix them with the unknown impurities obtained in the water, &c. Now this is not exactly what I proposed to do. I proposed to use a means of ridding the water of the noxious qualities of its impurities by adding a little silver to it first, and then, should any precipitate form, filtering it out, and proceeding to make up the bath with the clear solution. This I hold to be an effectual way of removing the ill effects of inorganic impurities in common water, and I do not think that the usual water supply of our large towns contains enough organic impurity to do any damage; at any rate, I do not think it contains so much as the ordinary run of distilled water.

On page 83 of the News is mentioned a "remarkable natural brine," containing about 2,500 grains of soluble salts to the gallon. It is mentioned in the same paragraph that the use of this water in photography would be unadvisable; and then the passage goes on to say, "This circumstance might furnish a practical answer to the doctrine lately promulgated." This, I suppose, refers to my having suggested the use of ordinary water in photographic operations. But it must be remembered that I recommended the use of *common water*, such as is used for domestic purposes; and as "remarkable natural brine" is not common water, I do not see how its unfitness affects the question any more than the general unfitness of all kinds of brine, sea-water included.

I have not yet made any experiments with the permanganate of potash, but it seems to me much more likely to prove an effectual remedy against "fog" than even using distilled water, because, it must be remembered, that even when distilled water is used, there is no guarantee against *some* organic impurities, which, being more or less volatile, distil over with the water. I hope to make some experiments with this substance soon, and to report progress in due time.

However, whether this or any other means be good, it does not alter the fact, that I have constantly succeeded without using a drop of distilled water in any operation.

## THE MAGIC LANTERN AND PHOTOGRAPHY.

BY JAMES MARTIN.

No. 7.

THE next step is the painting of the foreground. For this purpose the palette must be set with all the colours. The foreground objects are the castle, the water, the reflections, the masses of rock, the figures, the sandy ground, stones, herbage, &c.

Begin with the most prominent object, the castle. Paint in the shadows with brown madder and madder lake, adding a little blue to produce the clear grey appearance of worn stone. The details of the ground on which the castle stands may be made out by a tint of brown madder; the general colour of the ground may be made of brown madder and blue, with a tint of burnt sienna; madder lake and gamboge for the lights; madder lake, madder brown, and Prussian blue for the half lights.

Distant trees may be tinted with madder brown and blue, and the same tint, with gamboge, for the lights. Nearer trees must be painted with gamboge and Prussian blue; the lights with gamboge and madder brown. The stems of trees are generally of a warm grey, and may be painted with

either a tint of gamboge, madder lake, and Prussian blue, or madder brown and blue. It is easier and much more satisfactory to mass in the foliage of near trees with the brush, and then take out the lights with the point of the penknife.

Reflections of objects on the surface of water are painted with the same tints as the objects themselves, and is best done at the same time. Should the water have motion—either from the force of the stream, from wind, or other causes—the forms of objects are reflected very undefinedly; but when the water is still they will nearly approach, both in colour and detail, the objects by which they are cast. Those parts of the water which do not cast reflections must be painted with tints corresponding in colour, but more grey in tone, than the surrounding objects.

And now the painting of the picture will have been done down to the line of wall bordering the lake. Take care to soften and blend all parts that require it with the dabbers. The road is gently undulating, and on the sides opposite and under the wall the lines are broken by means of grass. In this part nearly all the tints of the other parts are repeated, and the lights are introduced in broad masses. As the foreground is supposed to be so near the eye that all objects of which it is composed are capable of being minutely distinguished, not only as to their general form and colour, but that also their structure and surfaces are plainly visible, it is absolutely necessary that they should have substance, force, and detail. Detail is not to be understood as merely a faithful rendering of objects by truthful drawing, but also to mean a description of their various components, surfaces, and materials, so as to give an appearance of reality.

Sufficient force also must be given to the shadows to cause the middle and remote distances to retire. The lights of the foreground objects must of necessity be stronger than those of any other part of the picture, and consequently the shadows, as wherever the highest lights occur they are always supported by the deepest shades.

The work of finishing a picture consists of softening and subduing, or invigorating and brightening, those parts which may require it, with a view to harmony and general effect. For this purpose all the colours are needed with the addition of black, which is only used to give sharp touches here and there for the sake of sharpness and decision, and should not be used at any earlier stage, for fear of lowering the tone of the whole of the picture. All the edges of reflecting lights nearest the eye must be brought up to their proper degree of brilliancy, and all the dark parts strengthened to their proper depth; in fact, all that could not properly be done at an earlier stage must now be completed.

The figures and dark markings of stones or other objects are left to the last, as the force and tone of the picture, in a great degree, rests with them. When the composition abounds with tints allied to purple—as in the present example—the introduction of deep blue, bright orange, and crimson in the dresses or accessories of the figures in the foreground contribute greatly to promoting the effect of the picture.

Glass painting is also executed in water colours, and sometimes by a mixed process of using both oil and water colours, thereby combining the transparency of the one with the richness and depth of the other. The instructions here given will be found sufficient to guide the learner in the use of either process. Through the kindness of one of our most talented artists on glass, I am enabled to give his mode of preparing gamboge producing a most intensely brilliant yellow of any depth desired:—Dissolve half an ounce of gamboge in one ounce of alcohol, shake well, and let rest for twelve hours; pour off the clear fluid, and add to it an equal quantity of turpentine; stand the mixture in a warm place until evaporated to one-half. Use this colour with varnish or oil colours as required.

The instructions here given are equally applicable to painting a photographic transparency, or a picture from the outline to completion. The light edges of clouds are best taken out by means of the needle points before mentioned.

In concluding this part of my instructions, it may be as well to make a few observations, attention to which may serve the pupil in place of experience. A judicious choice of subject must be made, otherwise a pleasing picture will not be the result. It should be at a first effort of the most simple kind, and more difficult subjects attempted as experience is gained. When a picture has been finished to the extent of the ability of the learner, it is better not to continue working upon it at the risk of muddling the whole, but rather to let well alone, as experience will be gained from each following picture; therefore every effort must be made that each succeeding one shall be better than the last.

114, High Street, Ilfracombe, Devon.

PICTORIAL EFFECT IN PHOTOGRAPHY;  
BEING LESSONS IN  
COMPOSITION AND CHILAROSCURA FOR PHOTOGRAPHERS.  
BY H. P. ROBINSON.

CHAPTER V.

"We cannot, as I have heard a great man express himself on another occasion, *see at sight*. A tolerably correct understanding of the construction and leading principles of an object is requisite, even to the seeing it properly."—*Opie*.

"Divested of design, art becomes a mere toy, a mechanical bauble, unconnected with either the head or the heart, uninteresting to the wise and good, unprofitable to all, and amusing only to the weak and idle."—*Barry*.

"Now do you see the point?"—*Md's History of a Mystery*.

It is not necessary that the ruling point should be absolutely at the side of the picture and under the extreme distance. It will be found, by an examination of the best landscapes,

to vary very considerably; but if it be an important object it will never be found exactly in the centre, or under, or in a line with any other important or prominent form of the same size or character.

The little sketch subjoined illustrates how balance may be obtained by opposition of lines and light and shade, referred to in the last chapter. The lines of the tree and foreground oppose the lines of the mountains, and the light on the near objects contrast the dark distance.

I take for further illustration this week a river scene, the construction of which the student will be able to perceive for himself. He will notice that it is diagonal in form, and that the balance is preserved by the boat. He will also notice that the masses produced by the principal trees is repeated by the sail, and the light cottage is echoed by the distant church.

It is always well to point out not only what to do, but also what not to do; and there is a slight example of what to avoid in the present instance. It will be seen that the cloud immediately behind the top of the central tree exactly follows the shape of the upper branches, and the cloud just above partly repeats the same form. Now, repetition is a valuable quality in art, and helps to give one part of a picture relation to the other parts; but repetition should consist of a faint echo, and not of exact imitation of lines or forms; this would look too much like artifice, even if agreeable to the eye, which it would not be; and art, however

much it may regulate the representation of nature, should never make nature look artificial.

Having, I hope, carried the student with me so far, I should advise him, at this point, to study good pictures and engravings, and, analyzing them for himself, see how far the simple rule—beyond which we have not yet got—of a small spot of dark, or an opposing line, acting as a balance to the whole, has been observed, especially in representations of landscape. I venture to assert that if he does this appreciatively for the first time he will be astonished at the regularity and frequency with which this principle is observed. A study of pictures at the present stage will have a better effect on the student than a study of nature, which could, without guidance, only produce in him a vague and unsettled taste. The study of pictures will make him acquainted with the methods by which they were produced, and guide him, by means of the general heads of composition, in his search for the numberless and hitherto unperceived beauties in nature. Taking the best known collection of landscapes I can think of at the present moment, and at

the same time that of the greatest excellence, and because they are by a man whose genius was sufficient to carry him above and beyond all rules if he had thought it right to reject rules, I would recommend the student to go to the National Gallery and make a careful examination of the Turner collection; or, if he is not able to see the original paintings, let him look through the last half-dozen volumes of the *Art Journal*, in which many of these wonderful pictures are admirably engraved. Let him forget, if he can, the gorgeous colouring, and the poetry and imagination which appears in so eminent a degree in Turner's works, and prosaically examine the construction of the pictures; or, rather, at present let him confine himself to the one point I have suggested, and when he is well grounded in that he may advance another step without fear of having to turn back.

Taking a few examples at random, let me first direct attention to the lovely Devonshire landscape, "Crossing the Brook," where the dog in the stream forms the balancing-point of the composition; then turn to the "Temeraire,"

and notice how the buoy performs the same function. In "Brighton Chain Pier," "The Sun Rising in the Mist," "Ancient Rome," "Spithead," "St. Michael's Mount," "Stranded Vessels off Yarmouth," "Fishing Boats," and other sea views, a buoy, barrel, anchor, boat, or piece of wreck will always be found doing the same duty. In the "Polyphemus," the dark prow of the galley cutting against the sky give wonderful power to that glorious sunrise. It is the same with the landscapes proper. Look at "Petworth Park," and observe how the dark form of the doe standing against the light in the foreground appears to have been the last thing done, but without which the harmony would not have been complete. In the curious picture representing a scene in Boccaccio, called "The Birdcage," it will be seen that a *white spot*—the music book on the ground—has been used to complete the balance. Notice how almost invariably he places his darkest dark in immediate juxtaposition with his highest light, of which his "Dutch Boats in a Gale" is a good example. Notice, also, and remember how, in his wildest fancies, painted when some people think his genius had deserted him or almost amounted to insanity, Turner strictly obeyed the simple rules of composition. For example, in the "Whalers," and that weird and wonderful picture of so prosaic a thing as a railway train, to which he has given the name "Rain! Steam! Speed!" And if the greatest landscape painter that ever lived could approve of these rules, and bend his great genius down to them, it is not for the tyro in art, or even the advanced student, to say: "Art is above rules, which only act as a drag on invention, and curb imagination."

Having arrived at this point, having attained some knowledge of elementary pictorial construction, and having observed in pictures how that construction has been observed by painters, the student may now turn to nature, look on objects indoors and out of doors, carefully analyse any object or group of objects that appear to have a pleasing effect, and he will find, in some degree, that the cause of the pleasure he experiences in looking upon them begins to dawn upon his mind. Let him ask himself whether, even at this early stage of his knowledge, he looks upon nature with the same indifference he formerly did, and if he has discovered new sources of pleasure, through the medium of art, with which hitherto he has been unacquainted, and for which he never cared. If he has discovered new sensations and new enjoyments, he has put these lessons to the purpose for which they were written, and may go on with those that are to come. If not, he had much better give the matter up, or "try back." I ask this question thus early because if the subject of the three last lessons be not quite mastered, all I have further to say will appear but as so much confusion.

#### CONCERNING THE OXYHYDROGEN LIGHT, AND THE MEANS OF PREVENTING EXPLOSIONS.

BY J. TRAIL TAYLOR.\*

ALTHOUGH for the production of photographic enlargements the lime light is, I believe, destined to be superseded at no distant day by the magnesium light, the latter, I fear, will not for many years to come enter into competition with the former for purposes where great steadiness is required, such as the exhibition of pictures in the magic lantern. At the present time, however, the lime light is extensively used in the production of enlargements; and, as it is the only light that can yet be used for purposes of exhibition, any means by which it may be improved will, I anticipate, be welcomed.

The lime light is of English origin. In the days of Sir Humphrey Davy a blow-pipe was introduced by a philosophical instrument-maker named Newman. It was a metallic vessel, into which air was introduced under pressure

by a force pump, the air being allowed to escape through a fine nozzle. The explosive and heating qualities of a mixture of two volumes of hydrogen and one part of oxygen were at this time well known; but Sir Humphrey Davy having discovered that the explosion from these gases would not communicate through small apertures, especially if under pressure, employed Newman's blow-pipe for effecting the combustion of the mixed gases. With this, Davy and Dr. Clarke, Professor of Mineralogy at Cambridge, tried numerous experiments, the heat obtained being the most intense at that time known. Lime, platina, strontia, alumina, rock crystal, quartz, flint, talc, emerald, lapis lazuli, plumbago, and other hitherto infusible substances, were all fused under this new and mighty power. When lime was brought under its action its incandescence was attended by a light of intense brilliancy.

By-and-by this property was utilised, and, among other applications, it was pressed into the service of the magic lantern. For many years, both in its heating and illuminating aspects, the gases were mixed together in a suitable bag or gas-holder, and many ingenious devices were had recourse to in order that no danger might follow their use; for Sir Humphrey Davy had, among his earliest experiments with this explosive compound, demonstrated that if certain conditions were disregarded, an explosion would result. His first and only explosion was produced with two quarts of the mixed gas communicating with the outer flame by means of a pipe an eighth of an inch in diameter, the gases being forced out under high pressure. On the light being applied to the burner the gas immediately exploded with a report like that of a cannon, the vessel in which they were contained having been shattered, and the *debris* projected with violence to a considerable distance.

One of the earliest experimentalists in the utilizing of the lime light was Lieut. Drummond, R.E., who, in 1826, communicated to the Royal Society a paper on the means of facilitating the observations of distant stations in geodetical operations, in the course of which he described a system of powerful illumination employed by him, which seems apparently to have been known previous to that time, viz., blowing a stream of oxygen through the flame of a spirit lamp. His using and recommending this light led to the designation "Drummond light" being applied to it. It may amuse you to be informed that I have three catalogues (issued within the past few years) of makers or dealers in magic lanterns, in which this light, described in 1826 by Drummond, is published as the newly-invented light of Mr.—, the dealer by whom the catalogue was issued. It may not be amiss to record here that, when compared with an argand burner, the Drummond light was found to possess thirty-seven times more intensity, magnesia only ranking as sixteen times. By a better selection of lime and more care in the adjustment of the flame, he afterwards increased the intensity of the light emitted from lime to eighty-three times that of the best argand burner of the period, supplied with the best oil.

For many years the mixed gases have been delivered through tubes packed with wire. Hemming's jet is an example of this. In later years the gases have been kept in separate bags, and allowed to combine just before issuing from the burner. In many cases they do not mix inside at all, the oxygen and hydrogen uniting *outside* of the burner. In such a case an explosion is quite impossible. It does not, however, require the aid of the photometer to discover that, when the gases are mixed previous to their emission, the light is much purer and more intense than when the other and safer form of burner is used.

In what follows I shall assume that if the best possible light be desired, the oxygen and hydrogen must be brought into contact previous to their emission from the burner.

If the gases are mixed only inside of the jet, no supply of it being kept in store, where, it may be asked, lies the danger of an explosion, or, at any rate, one of any magni-

\* Read at a meeting of the South London Photographic Society, February 13, 1868.

tude, seeing the explosive material is so small? There are various sources of danger, such as the accidental presence of some other gases than hydrogen or oxygen in their respective bags. If the gases be pure, and kept separate and under uniform pressure, I do not believe an accident will occur; I have not, at all events, heard of any. But if the weights on the bags be not equally adjusted, the bag which is under the greatest amount of pressure has a tendency to transmit its gas to the other, unless the orifice be sufficiently large to allow both gases to escape into the atmosphere. Should, however, the orifice be stopped by a particle of dirt, or by any other means, diffusion of the gases will take place with alarming rapidity. That it does so repeatedly, even under the most favorable circumstances, is attested by the frequent snappings in a mixed gas burner.

The interposition of several layers of wire gauze is supposed to prove a preventive measure. It is argued that, as a common flame will not pass through a small orifice, so neither will the flame of oxyhydrogen gas. There is a considerable difference between both the nature and tenacity of certain flames. Sir Humphrey Davy found that a wire tissue of one hundred apertures to the inch (made of 1-60th size wire) will intercept the flame of a spirit lamp, but not that of ordinary hydrogen, although both these flames have been considered to be very similar in their tenacity. I am almost prepared to assert that the flame of oxyhydrogen will pass through any body that will transmit the gas in a practicable quantity. Mr. Gurney has sent the oxyhydrogen flame through a thin slab of plaster of Paris, and I have myself sent it both through porous wood and a wire-packed tube; hence I conclude that safety must be sought for in some other direction than in the interposing of obstacles which assuredly would prove futile in resisting the passage of the flame.

Where, then, is safety to be sought for, and by what means is it to be secured? The following principle will enable us to arrive at a satisfactory reply to this question:—If the orifice of the burner be small, and the gas from one reservoir be not allowed to get into the other, no explosion can take place in either bag. The small snapping explosions in the burner are innocuous; I refer especially to the explosion of the bag, which, if of large capacity, will readily unroof a house and scatter destruction all around. Mr. Gurney found the only means of security to consist in passing the gases through water. I have tried this, and, although satisfactory for blow-pipe experiments, it is not so for lighting purposes.

On the occasion of a life very valuable to science being nearly sacrificed by an explosion, I was requested to devise a burner by which an explosion would be rendered impossible either by carelessness or design. In endeavouring to accomplish this I found only one thing to be necessary, viz., that the gas pipe from the bag to the burner should transmit the gas in one direction only; that to secure this one or more self-acting valves must be interposed in the current of the gas, and that these should only allow the gas to pass when under pressure, when, consequently, no danger could result. For instance: suppose that the weight accidentally falls from off the hydrogen bag, the sudden release of the bag from pressure causes not only the cessation of the gas supply, but also a back-draw, which, were there mixed gases in the bag, would be instantaneously followed by an explosion. But the hydrogen being pure, nothing happens at first beyond the going out of the light. Simultaneous with this, however, the oxygen rushes into the hydrogen bag, which is now relieved from pressure, and, on the subsequent application of the flame, the bag is in a favourable condition to explode.

If there were a self-acting valve, such as that to which I now direct attention, nothing whatever could happen but the extinction of the light; for concurrently with the withdrawal of the pressure caused by the weight falling off the bag, the valve would close, and the greater the back-draw into the bag the more certainly would the valve act to pre-

vent it. But, moreover, for the gas from the one bag to get access to the other would be a simple impossibility.

This method of thoroughly preventing an explosion is not a mere crude suggestion. I have had it in use for some years. After I determined upon adopting valves of this description I had some made, and I tried their efficiency in every possible way. In order to subject them to a crucial test I had a small bag (full of the mixed gases) so constructed that, when the flame was issuing from the burner and everything was ready, by pulling a string I could at once remove the pressure, and cause the bag to suck air in as if it were a bellows opening, and that, too, with a burner and tubes quite unobstructed by any kind of packing.

I shall now show, by means of diagrams, some of the several kinds of safety-valves I have had in use. I have varied their forms to suit the particular circumstances under which I employ them, but the principle is the same in each, viz., a light flap or valve of any light, unoxidizable substance, such as aluminium, kept, either by the force of gravity or by a light spring, against a plate of metal having a hole sufficiently large to transmit the gas, which it will do in one direction only, by its elastic force raising the valve, and thus permitting its egress. When, on the one hand, the pressure on the bag is withdrawn, or, on the other, a greater degree of pressure is exerted outside of the valve, it immediately closes; and, as I have already stated, the greater this opposing pressure the tighter is the valve closed, and the more impossible is it for an explosion to take place.

As it is impossible to show the action of these valves when prepared for actual service, Mr. F. W. Hart has kindly prepared some models in glass, and, by means of the small elastic bag attached, the action of each valve respectively will be seen, and the perfect safety of the system demonstrated.

These valves cost only a trifling sum, they occupy little space, can be attached to all existing burners, and, on these grounds, coupled with the safety secured by their use, I recommend their adoption. One of them placed inside the tube near the bag, and one at the stopcock at the back of the lantern where the elastic tubing is attached to the burner, will prove a sufficient protection for each bag.

## CONCENTRATION OF LIGHT IN THE STUDIO.

BY E. DUNMORE.\*

It is a popular idea that Continental photography owes much to the excellence of the light, altogether independent of the skill of the operator. I have brought this evening for your inspection a few pictures, taken under very disadvantageous circumstances, both of light and temperature, during the past month, exemplifying that the *purity* of the light is not a *sine qua non* for the production of a brilliant photograph. The exposure, which ought in a good light to have been about a minute, has been never less than two, and in one or two cases over four minutes. The time for printing has been from one to three days each print. I do not exhibit them as "uncorrected" photographs; for I believe no large portrait was ever made that could not have some touches advantageously added to soften a hard line or sharpen a soft one. Where this could be done I have had it done, and am a firm believer in its perfect legitimacy. The negatives were taken with the smallest amount of diffused light in the glass house possible to work with, the models being lighted by about a yard square of clear glass, some even with less. Had it been bright summer weather, of course less clear glass would have sufficed with advantage even than this.

## INFRINGEMENT OF COPYRIGHT BY PHOTOGRAPHY.

WE find details in the daily papers of a case of extensive infringement of copyrights by means of photography, in which fines to the extent of £130, being £5 each for twenty-

\* Read before the London Photographic Society, February 11th, 1868.

six separate piracies, were inflicted. The case was heard at Guildhall Police Court, before Sir Robert W. Carden, on Monday last.

Samuel Benoni Beal, a stationer and dealer in photographs, carrying on business at 47, St. Paul's Churchyard, appeared before Sir Robert W. Carden, to answer thirty-four summonses taken out against him by Mr. Henry Graves, of Pall Mall, the eminent publisher and engraver to the Queen, for unlawfully selling, on the 31st of July last, seven pirated photographs of a painting called "Ordered on Foreign Service," four of "My First Sermon," and two of "My Second Sermon," knowing the same to have been unlawfully obtained; and for unlawfully and fraudulently selling one photograph of "His Only Pair," having thereon the name of the complainant, who did not execute or make such photograph. Also for unlawfully selling, on the 12th of August last, seven copies of "Ordered on Foreign Service," four of "My First Sermon," and two of "My Second Sermon," knowing the same to be unlawfully made; and likewise for unlawfully and fraudulently selling three photographs of "His Only Pair," two of "The Plough," one of "Saved," and one of "Taming the Shrew," having thereon the name of the complainant, who did not execute or make such photograph.

Mr. George Lewis, jun., of Ely Place, appeared for the complainant (Mr. Graves), and Mr. Francis for the defendant.

Mr. Lewis, in opening the case, said there were thirty-four summonses against the defendant, but he would take them as under two heads, as there were only two purchases. In this instance there was no excuse for the defendant, for he was well acquainted with the photographic law, and had actually started, in conjunction with Mr. Ashford, an association for the purpose of protecting the photographic process of pirating works of art against the attempts which the owners of registered copyrights might make to prevent them carrying on their lucrative trade. Their names were attached to the pamphlet advocating the society, and they had been receiving subscriptions for the purpose of protecting themselves under the shadow of that society. Mr. Lewis then explained the case as given in evidence, and said that to detect the defendant and others it had cost Mr. Graves over £1,000. One of Mr. Graves's engravings had cost him £25,000, and before he could get the copies round to the subscribers the photographs of it were being sold for 2s. 6d. each, and it laid Mr. Graves open to the remark that what he was selling for £10 10s. others were selling for 2s. 6d.

John Cattermole, in Mr. Graves's employ, proved the purchase at defendant's place of business of four copies of the "My First Sermon," seven of "Ordered on Foreign Service," two of "My Second Sermon," and one of "His Only Pair."

The engraving of "My First Sermon" was put in, and Mr. Graves said that he paid £1,000 for the copyright of that engraving, and the photographs were selling for 2s. 6d.

Mr. Cattermole said he went to the defendant's on the 12th of August for a parcel, and it was made up for him at the back of the shop. He paid defendant £5 8s. for it, and received a bill and receipt for it. That parcel contained seven copies of "Ordered on Foreign Service" (the original picture of which was burnt at the fire at Mr. Graves's when the Italian Opera House was burnt down), four of "My First Sermon," two of "My Second Sermon," three of "His Only Pair," one of "Saved," two of "The Plough," and one of "Taming the Shrew." They all bore the name of Mr. Graves and the names of the painter and engraver. He received the following letter from Mr. Beal, which he wanted him to sign:—"I hereby signify, for your satisfaction, that the goods purchased by me of you at various times are your own stock, and not those copyright pictures which I am buying elsewhere. This is signed, at your request, to avoid any complication in the future from any dealing in and buying pictures you do not sell on copyright grounds." On the 5th of February he wrote agreeing to sign the document, and ordering more goods, and, on the 6th, received a note from the defendant agreeing to sell more, but asking, "How about the parcel already looked out?" Several letters passed between them, and in one, on the 15th of February, defendant said: "Possibly I might get, on your sudden demand, any quantity enough for you by a little notice. The great thing is reliability."

Mr. Graves proved the registration of the various pictures, and stated that he gave 200 guineas for the copyright of "Ordered on Foreign Service," and the engraving cost 200 guineas more. The various photographs were not made by him nor by his order. If that piracy were allowed to go on it would ruin engraving for the next half century.

Mr. Lewis asked for thirty-four penalties of £5 each, or in default two months' imprisonment on each fine.

Mr. Francis contended that it rather benefitted than injured Mr. Graves to have his pictures photographed, as it was an advertisement for him. He, however, submitted that the Act would not apply to "His Only Pair," "The Plough," and "Saved," as they bore date before the Act under which they were proceeding was passed. The photographs did not purport to be published by Mr. Graves, but to be a copy of an engraving published by Mr. Graves. He then took exception to the certificate of registration, as it did not contain a description of the picture, and was, therefore, not in accordance with

the Act of Parliament. He next contended that the defendant was summoned for selling a photograph of the painting, whereas the evidence showed that it was a photograph of the engraving. He then came to the question of penalties, and said that only two sales had been proved, and that, therefore, only two offences had been committed, for which he had the power to fine the defendant £10 each; but he denied that the magistrate had power to make thirty-four offences of them.

Mr. Lewis contended that the sale of every photograph was a separate offence. As to the photographs being taken from the engravings, the Act was passed expressly to meet that case, for it was well known that they could not get at the pictures to photograph them. With regard to the certificate, it stood as *prima facie* evidence until it was rebutted.

After a lengthened argument between Mr. Francis and Mr. Lewis, Sir Robert W. Carden said he would adjourn the case, and give his decision the next morning.

On Tuesday morning, on the opening of the Court,

Sir Robert W. Carden said: I am very glad I delayed giving judgment yesterday, for it has given me an opportunity to weigh well all the arguments which were used by the learned counsel for the defence. I am certainly in some little difficulty with regard to eight of the summonses. The complaint is, "did unlawfully sell a photograph, to wit 'The Plough,' having thereon the name of the complainant, who did not execute or make such photograph." Now it appears to me that that wording is so ambiguous that I should not like, unless Mr. Lewis can relieve me from the difficulty, to convict upon those eight. If it had said, "having thereon the name of a person who did not execute or make such photograph," I think it would have had more weight; but as it is at present I should not like to take upon myself the responsibility of convicting upon those eight. Now there is no doubt that a great and cruel fraud has been committed upon the prosecutor, Mr. Graves, by the mean and dishonourable system of piracy which exists, and has existed for some time, to so ruinous an extent that, if not checked, it would inevitably lead to the destruction of the beautiful art of engraving. The learned counsel, Mr. Francis, has spoken of the great value of photographs, and everybody must have been struck with the beauty of the specimens submitted to us yesterday; but in proportion to the value of the production we must give protection to the holder of the original design. We know that there is great profit arising and great danger in obtaining that profit by the sale of these articles, and it is most difficult to ascertain the wholesale agent who remits them to the retailers. I have been looking into the evidence, and fairly weighing the ingenious arguments of the learned counsel. Mr. Beal, curiously enough, has actually inaugurated a society for (as it appears to me) the protection of himself from the pains and penalties of doing wrong, and he will no doubt repay himself from the funds of that society. I did not read the book last night, but certainly the preamble was most extraordinary, and appears to be for the protection of fraud. No doubt it is very difficult to prevent the importation of foreign photographs, because there are always dishonest men, with no character, willing to traffic in anything if they can make money by it; but do not let it be said that such practices are pursued by men who are regarded by their neighbours as respectable and fair-dealing tradesmen. One would hardly suppose that it could be so. I do not think it is fair for one man to live upon the brains of another. We all live by our own brains, and I think we ought to be well paid for the work of our imagination. Therefore I think it a very hard case that one gentleman should be so robbed by another. I call those houses which receive these photographs as no better than the receivers of stolen goods, and this they must know perfectly well; and Mr. Beal must have known it perfectly well, as is proved by the secrecy which is observed in selling, and also by his being under the protection of the society. Under these circumstances I shall take off the eight cases, reducing the number to twenty-six; but in each of these I inflict a fine of £5, or, in default, seven days' imprisonment, which will amount to £130, or six months' imprisonment. I hope this will be a warning to all those who endeavour, by the advantages belonging to art and science, to encroach on the property of other people.

Mr. Francis asked for a case for a superior court on three grounds: first, that there was a defect in the registration; secondly, that there was no evidence that the photographs were copies of the pictures or the design thereof; and, thirdly, that the magistrate had no power to fine on every individual photograph.

Mr. Lewis replied; and, after a very animated discussion,

Sir Robert W. Carden said he thought the objections were frivolous, and refused to grant a case.

The defendant then paid the fines under protest, so that he might apply to a judge at chambers on those points.

## Proceedings of Societies.

### FRENCH PHOTOGRAPHIC SOCIETY.

THE January meeting of the Society was held on the 17th ult., M. BALARD occupying the chair.

M. DAVANNE, on behalf of the Administrative Committee, notified to the members the loss they had sustained by the death of the Duc de Luynes, who had been one of the founders of the Society, and likewise one of its most ardent supporters. He stated that a letter of condolence had been drawn up in the name of the Society, and transmitted to the late Duc's grandson, who had received the note with much regard.

M. DAVANNE also announced the death of M. Claudet, who was one of the earliest photographers; he was among the first to engage in the study of Daguerreotype, and to put that process into practice; and he had, during his lifetime, contributed to the art many important improvements.

A letter was read from Sir David Brewster, thanking the Society for the honour they had conferred upon him by awarding the medal of the Society for his researches, and forwarding for the acceptance of the members two copies of his works on the stereoscope and kaleidoscope.

M. DAVANNE announced that, in consequence of domestic affliction, their esteemed President, M. Regnault, would not offer himself again for re-election. M. Regnault had been President of the Society for the last thirteen years, and, as a token of respect to one who had devoted so much of his time and labour to their welfare, the Administrative Committee proposed that he should henceforth be styled Honorary President to the Society.

This proposition having been unanimously agreed to, M. Davanne read the Report of the Committee appointed for the distribution of awards to deserving photographers during the year 1866. The Report stated that the year in question had been very unfruitful in regard to the discovery of new processes, many photographers doubtless being unwilling to bring forward their improvements pending the duration of the Exhibition. Several names had been considered as to their claims to receive the Society's medal on the score of the superior excellence of their productions; but as these gentlemen did not impart their method of working to others, and as it was the principal aim of the Society to encourage the vulgarisation of the art; no appropriation of medals was recommended.

M. BRAUN presented the Society with ten albums containing photographs in pigments of works of art in the Vienna and Weimar galleries.

M. DESPAQUIS exhibited some carbon prints taken upon paper coated with a collodion varnish.

M. BRIORS exhibited to the Society samples of the coloured and uncoloured collodion varnish.

M. DRIVER presented to the Society a collection of photo-engraving, produced by a process of which he has not yet published the details.

M. CURMER described to the Society the details of a small portable laboratory, invented by himself, which, by simplifying the manipulations and economising the apparatus employed, he has been able to reduce within the most limited dimensions. He presented a model to the Society.

The proceedings then terminated.

## Correspondence.

### M. SALOMON'S PORTRAITS.

SIR,—Although the controversy as to the source of superiority in M. Salomon's pictures has already occupied more than a reasonable amount of public attention, there still remain some questions which should, I think, be answered.

1. Has M. Salomon ever said that all his pictures were untouched?

2. Has any competent authority said his pictures were all untouched, or, as a rule, untouched? I ask this question because I see that a correspondent in the *British* of Jan. 31, signing "Scrutator," affirms that you have made such statements; and as I have only recently commenced taking the News, and in the numbers I have read I find that you constantly affirm that many of the pictures are touched, I am curious to know the cause of the discrepancy. "Scrutator" refers to pages 481, 534, and 545 of the News, as containing statements that these pictures are untouched. The first passage is quoted, and it distinctly states that M. Salomon's portraits are untouched.

3. Has any one, whose word or judgment would carry weight

with photographers, seen the print which "Scrutator" says he analysed; or is there any evidence, beyond an equivocally worded anonymous letter, to prove that any such examination was made?

4. If it be true that such examination was made, and that one print was found to be touched, does it follow that all were touched?

5. Has any one else produced similar results by means of touching?

6. What is touching? This question seems absurd; but the word seems of doubtful meaning. In its ordinary sense it is understood to be applying a few touches to remove defects or produce improvement, and all photographers are supposed to do it. Young ladies for touching and mounting are in frequent requisition. But when used in reference to M. Salomon's prints it seems generally to imply what used to be understood by "working up" or covering the photograph with sepia or Indian ink.—Yours truly,

VERITAS.

[We will answer our correspondent's questions categorically, although we think that it should scarcely be necessary to answer any of them. 1. We have repeatedly stated that M. Salomon has not put forth any statement or question of touching at all. 2. We have from the first very distinctly stated that some were a little touched, some considerably touched, and some untouched; also that the best were untouched, and that the characteristic excellence was in nowise due to touching. We have constantly repeated this statement as to the touching, and have never said anything which, even by implication, could be understood as a statement that all the portraits were untouched. We have turned to the pages of the News to which you say "Scrutator" refers as containing statements that the pictures are untouched, and find that he has been guilty of something very like dishonesty. The passage quoted as from the News, p. 481, is, in reality, from the *Times*; it is quoted in the News at that page, and duly accredited to the *Times* Correspondent. The other two references are to our own articles, and contain no such statement. They contain allusions to special pictures which we had ascertained to be untouched. 3. We have not heard of any one who has seen the "analysed" print. 4. Of course not, any more than because one print has been found to be untouched that all should be considered so. 5. We have not heard of any one who has produced similar results by touching or any of the proposed "dodges." 6. By "touching," we presume is meant the removal of blemishes or supplying of deficiencies, which can be effected without interfering with the distinctive photographic characteristics of the photograph, a process which most careful photographers apply to such extent as they can to pictures. "Working up" is rather a mode of finishing, in which the photograph is made the basis of monochrome painting.—Ed.]

### SILVER PRINTING.

DEAR SIR,—It is with much gratification that I notice Mr. Bovey has undertaken to write a few practical articles on the subject of printing. How important the process, and yet how few really possess that practical knowledge that is indispensable to success! Many, of late years, have entered photography, and with one stride rushed into the operating room, thinking all other departments of very minor importance, consoling themselves with the idea that a boy, or even a young girl, at a few shillings per week, can be trusted to undertake the printing, toning, &c.; and if any failure occurs it is either the bad paper, impure gold, hard water, or all together, that are blamed, and, as usual, all are brought in guilty except the real defaulter.

Again, how many are allowed to conduct these processes who go to work in a most mechanical way, treating all negatives alike, as well as all papers, whether strongly salted or not! During the last ten years I have heard it frequently remarked by operators of experience, when asked why they always take such hard negatives, and, as a rule, considerably over-intensify them, their answer has been, Because the printing is done by young, inexperienced hands; and that unless the negatives are so thick with deposit in the lights that it is almost impossible to over-print them, they are sure to be spoilt. No one can become doctor of law, science, or medicine, without first thoroughly accomplishing the preliminary stages to that degree; and no one should consider himself a photographer when he alone understands the process of taking negatives.

But those that are in this unfortunate position have a remedy,

which they would do well to avail themselves of, as it would put money into their pockets as well as advance their reputation. The remedy I refer to is simply this: Put your printing out. In these days, when there are men of recognized ability who undertake printing for the profession, and can always ensure the same good, uniform results, through working (like our friend Mr. McLachlan) upon principles based on experience, should be the means of supplying the lack of that knowledge so evidently wanted in many who call themselves photographers, and who are either too proud to own their inexperience in this department, or fancy it too expensive to put their printing out, which latter is a great fallacy, inasmuch as if they reckoned up what their failures cost them, and the inevitable result of sending out inferior work, they would come to the conclusion that they would be in pocket by availing themselves of this remedy.

I would mention here, in support of this, that I was much pleased the other day with the frankness of a letter addressed to a trade printer of great experience from a photographer in the country. He stated that he had a fair knowledge of operating, and could take good negatives; but, knowing nothing of printing, would feel obliged if — would undertake the same for him regularly. To own one's ignorance is wise, and will in the end bring its reward. One has only to take a cursory glance at the albums found upon the drawing-room tables of this vast city to see how much still remains to be accomplished before photography can hold a position among the arts that it should be the desire of every photographer to make for it. The bad style that many have of vignetting is certainly inexcusable after all that has been said and written on this subject; however, these faults and failings are not, as a rule, to be attributed to those who have taken up with photography as an art, but to those who have simply entered into it as a trade; and the sooner they quit what should be a profession, and not a trade, the better for real photographers and the better for art generally.

Thanking Mr. Bovey for taking up the subject in a practical form in your valuable pages, I remain, yours very truly,

GEORGE HOOPER.

## Talk in the Studio.

**DEVELOPMENT EXHIBITED BY THE MAGIC LANTERN.**—A pretty lecture experiment was exhibited, on Friday evening, at the Royal Institution, by Professor Roscoe, in which the process of developing a latent image was shown to an audience on the screen of a magic lantern. A wet plate having been exposed to the light of magnesium wire, under a negative, and a latent image produced, the prepared plate was then placed in the groove of a magic lantern, a red glass being interposed between it and the light. The developing solution being then applied to the film containing the latent image, the gradual appearance of the visible image, as development progressed, was seen by the whole audience, as projected on the screen. When completed, and the red glass was withdrawn, the transparency being illuminated with the brilliant oxyhydrogen light, the effect of an image which had its birth under their eyes had a very striking effect on the audience. We presume that the operation of development would be effected by immersing the prepared and exposed plate in a suitable glass dipping-bath containing the solution, and then placing the whole *in situ* in the lantern.

**SPLITTING OF FILMS.**—Mr. T. Stothard sends us the following regarding the splitting of films:—"I beg to state the result of some observations on this subject. I had been troubled with scratched splitting of the film, and, considerably annoyed, sought for the cause. I found that negatives taken on the same day, and under similar circumstances were not all damaged. Those with a portion of the film removed all round for neatness and security (?) before varnishing, had gone in some cases; of those varnished with the same varnish (Thomas's), but not cleared at the edges, fewer; and, on looking through my several boxes of negatives taken during the last two years, I found that none had gone of those not varnished, but coated with a preservative albumen solution, the receipt for which I am indebted to Dr. Holden, of Glenarm, N. Ireland:—

Albumen	...	...	...	white of 2 eggs
Water	...	...	...	1 ounce
Liquid amm. fortis	...	...	...	15 minims,

filtered through cotton-wool, poured on to the plate after it is fixed and washed, and while still wet. *Advantages:* it sinks into and supports the film; is of no appreciable thickness, and the negative therefore is in closer contact with sensitive paper while printing; and, as I find, freedom from cracking."

**THE FORTHCOMING SOLAR ECLIPSE.**—At the anniversary meeting of the Astronomical Society, on the 14th inst., the Rev. C. Pritchard, President, made the following statement:—"The present year will be signalized by a total solar eclipse of almost the greatest possible duration. As probably centuries may elapse before we shall have again an opportunity so unexceptionably favourable for observing the peculiar phenomena which are only to be seen during a total eclipse of the sun, it will be a source of gratification to the Fellows of the Society that two well equipped expeditions have already proceeded to India for the purpose of making observations during the eclipse of August next. One of these expeditions, originated by our Society, is under the superintendence of Major Tennant, of the Great Trigonometrical Survey, who will be assisted by Captain Brandreth and three non-commissioned officers of the Royal Engineers. It is proposed to take photographs of the eclipse, for which a reflecting telescope of the Newtonian form of construction, furnished with a silvered glass mirror, has been provided. The pictures will be taken at the focus of the mirror, without any enlargement, by an eyepiece; as was the case with those taken by Mr. Warren De la Rue in Spain. Major Tennant is also provided with suitable apparatus for observing the spectra of the red prominences and of the corona, and for analyzing the light of these objects by polarization.

**THE PHOTO-GALVANOMETER.**—A paper was recently brought before the Royal Society by Professor Airy, on earth currents. Currents of electricity are always running to and fro in the earth, sometimes entering the telegraphic wires, and sending streams of electricity through the lines of sufficient strength to overpower the working batteries, to stop telegraphic news for the papers, and to send unreadable messages on their own account. Such electrical storms are a source of great loss to telegraph companies while they last. A few miles of wire were, therefore, erected from Greenwich Observatory, to measure and observe these currents, which are made to move a galvanometer to and fro ere they enter the earth. The galvanometer is mounted in a darkened room, and its needle reflects a ray of light as it moves upon a sheet of photographic paper, whereby variations in the current are continuously recorded. Professor Airy's paper, read before the Royal Society, pointed out that some connection exists between the movements of the earth currents and the declination magnetometer, for both are affected at nearly the same time.

**PHOTOGRAPHS OF THE BELGIAN VOLUNTEERS.**—The civic guards of Liege, following the example of their Antwerp brethren, have resolved to present Miss Burlett Coutts with their photographs, enclosed in a beautifully bound ornamented album.

**PHOTOGRAPHY AT THE AMERICAN PATENT OFFICE.**—In the annual report just issued from the Patent Office at Washington it is stated that henceforth photography will be used for reproducing and multiplying the designs of patented articles. The Reporter says:—"The drawings now number over 100,000, and are becoming torn and soiled by the constant but legitimate wear to which they are exposed. Photography seems to offer the only means for renewing them. For some time past I have had it in contemplation to have photographic copies of uniform size made from the current issues and the drawings of former patents, so as to furnish to each examiner a copy of all drawings appertaining to his class, enabling him to consult them without going to the draughtsman's room, where the space is insufficient for the purpose. It has been my purpose to commence by photographing each week the current issues and several hundreds of the back issues, so as gradually to accumulate a full copy of the record, and, where a drawing may be lost, to take a photographic view of the model which might stand in its place. The copies thus made would be of even size, and smaller than the average of the originals, which would enable them to be placed in compact form, and greatly to economize the room occupied by them."

**SEDUCTION IN A PHOTOGRAPHIC STUDIO.**—A case was heard in Court a few days ago—one of a class, happily, not common in photography—in which a photographer residing at Mile End was the defendant in an action for seducing a young lady who was assistant in the reception-room. The Court awarded £250 damages.

## To Correspondents.

**ENQUIRER.**—The card enclosed undoubtedly contains hypo, or some compound yielding sulphur, causing fading of the print; we should scarcely have been prepared, however, for such a deplorable amount of fading and discolouration from such a cause as the card exhibits. It appears, however, very probable that the deplorable condition of the picture is due to the presence of the hypo. 2. The cracking in the negative film, of which you send us an example, is curious and of a kind not common, although we have seen a similar case before. The varnish appears quite intact, whilst the film of collodion is clearly divided. We cannot satisfactorily explain the cause.

**J. L.**—You must go to more authentic and trustworthy sources for information before you base arguments thereon. The "fact" that M. Adam-Salomon did not receive medallistic honours at the French Exhibition, or that it was because he admitted that his photographs were touched, is not a fact, but a fabrication. M. Salomon received a silver medal for his photographs at the Exhibition; and he was not asked any questions by the jurors as to the touching, nor made admissions of one kind or another. The extent to which any of them is touched is, in most cases, easy enough to distinguish, and neither requires admission or denial, as it in no wise affects the peculiar excellence of his pictures; nor does the question of touching affect the lesson which photographers should derive from them. You must not run away with the notion that the sketches in question give the slightest idea of the pictures; their real charm—which consists chiefly in the grand masses of light and shade—is entirely lacking. You must see the prints themselves to form an idea.

**ALCOHOL.**—Methylated spirit and methylated ether are frequently used by manufacturers of collodion. Redistillation is the only effectual method of rectifying spirits. By keeping it in a bladder, water passes through the membranous bag, leaving the spirit behind, and so strengthens it by evaporation of the water; but this is not practical upon any large scale.

**A SUBSCRIBER.**—Refer to our advertising pages, and after selecting such as appear likely to suit you, indicate them in your next by a figure or letter; we can then advise you without making invidious distinctions.

**T. STOTHARD.**—A varnish of which the chief ingredient is boiled oil will make calico waterproof, and also transparent; but all such materials for making fabrics waterproof eventually become yellow. Thanks for the hint, which we give in another column.

**J. A.**—White blinds will, of course, answer a similar purpose to stippling the glass. We approve your resolution, and hope you will have success. 2. Your doublet or portrait lens will answer best for enlarging and copying.

**W. J. A. G.**—It was curious enough that you should get any presentable result in such a mode of operating; but, as you remark, the prints would not possess value for practical purposes. The possibility of performing the ordinary dark-room operations in the presence of any proportion of actinic light depends, of course, for immunity from injury, partly on the sensitiveness of the plate, and partly on the rapidity with which the operations are performed. Your letter did not contain the example of a fabric for dark tent, concerning which you make inquiry.

**A PROVINCIAL PHOTOGRAPHER.**—To begin with, the focus of your condenser—eight inches—is much too long for convenient use in enlarging with artificial light; one with a focus half that length will answer better. The artificial light should be placed at a distance from the condenser a little less than its solar focus, and the focus of the condenser, bringing the light to a point, should be on the front lens of the combination used for enlarging. The condenser must be larger than the negative to be copied, and the negative should be sufficiently near the condenser to get perfect illumination all over. The further from the condenser it is placed the smaller will be the portion of it illuminated, as, of course, the cone of rays diminishes in diameter as it leaves the condenser.

**C. W. S.**—The unequal development of your enlarged prints is due to unequal dryness of the print when the developing solution is applied. In the formula which you quote it is intended that the paper should be used wet, in which case you would have no inequality. 2. The formula in question is suitable for development, but not for printing out. In the production of enlargements printed fully out, without development, you cannot do better than use the ordinary albuminized paper printing process, and tone in the regular way. The only modification which enlarging renders desirable is the use of a more highly salted albuminized paper and stronger silver bath than usual, in order to secure greater sensitiveness.

**WATERLOO.**—As a general rule, the transparent positives neces-

sary for producing enlarged negatives do not need intensifying, as great density is not required, but rather softness and fullness of detail. We cannot tell you the reason why your positives are weak without seeing them, or knowing something of the means whereby they are produced.

**TONY.**—You will find a useful article on the Positive Collodion Process in our YEAR-BOOK for 1864. 2. Bottles which have had solutions of silver or gold may be cleansed with strong cyanide of potassium; those which have contained iron solutions with sulphuric acid; those which have had collodion with ether and alcohol.

**J. C. D.**—The general proportions of your proposed studio are very good; but it would be better a foot higher at the eaves and one or two higher at the ridge. 2. For the dark room, a skylight is quite inadmissible; you must have the light from a window in front of you, in order, with convenience, to examine the progress of development in producing negatives.

**R. J.**—Theoretically, the back lens of the triplet for enlarging should be placed next the screen, and the front lens next the light; in practice we believe that it does not much matter. 2. It is better to place the negative in a frame, which will intercept all light not passing through it. 3. It is important that the focus of the condenser should fall on the front lens—that is, the lens next the screen—of the enlarging lens. 4. If you use a solar camera for producing enlarged negatives, use the condenser if you have sunlight, and the exposure will be exceedingly short. If there be no sunlight the condenser is useless. 5. For producing enlargements on paper, by means of the solar camera, using the paper wet from the sensitizing bath is the best plan. As a rule, with sunlight the exposure will be decidedly shorter than with artificial light, using the same process. 6. Of course you must focus by the lens. The negative must be in such a relation to the condenser as to be imperfectly illuminated. If it be too far off the diameter of the cone of rays will be insufficient to illuminate the negative all over; if too close to the condenser, intensity of illumination is lost. The best position is that where the diameter of the cone of rays just covers the negative. A compilation from our pages of the material to which you refer would doubtless be useful to many; but it is uncertain that its publication would be remunerative. It may possibly be done, however.

**T. C. (Brixton).**—With the exception of Col. Sir H. James's book there is no work published on photozincography or photolithography. The best definite information you can obtain will be found in Mr. Baker's article in our YEAR-BOOK for 1867. Col. James's book is published by Longman and Co.; the price is 12s. 6d.; it is a good book, but does not enter into minute technical details or manipulations.

**W. BONEHILL.**—The photograph from painting of a prize ox was duly registered.

**AMATEUR, A. W.**—It is a somewhat difficult matter to advise you upon, as the best professional photographers are generally indisposed to be troubled with pupils, and those willing to receive them are not always the most capable. There are, however, exceptions. We will make some enquiry and let you know privately.

**AMATEUR (Pau).**—We suggested that the plates might have been used before, because the lines seemed much like the result of lines of a former image imperfectly removed from the plate. The suggestion you make as to the constant moving of the plate up and down from the moment of immersion, and the possibility that the plate might not be perfectly immersed each time, will, we think, readily account for the lines, which, if we understand rightly, were not in the direction of the dip, but at right angles to it. As a pause in the immersion of the plate will cause a line, so repeated imperfect immersions immediately after the first immersion would produce a series of lines. We shall be glad to hear any further details.

### PERMANGANATE FOR RECTIFYING OLD BATHS.

FROM various communications which have reached us it appears probable that the use of a permanganate for rectifying old nitrate baths containing injurious organic matter will become common, as it is, in the various cases brought under our notice, successful. A few further observations on the best mode of proceeding seem, however, to be desirable, to aid experimentalists in securing the best result. One of the chief errors to be avoided is adding excess of the permanganate, through impatience to secure a speedy effect. If the permanganate be added cautiously and in small quantities, the organic matter, especially the most injurious part of it present, will be oxidized and destroyed; and no further result will take place. But if excess of permanganate be added, and especially in strong solution, permanganate of silver will be formed, and as this is soluble in water to the extent of about four grains to the ounce, a portion will remain in solution. The precise action of this salt in the bath remains to be ascertained; but it is probable that it will be analogous to that of nitric acid. But another danger may, possibly, arise from its presence: the saturation of the bath with a comparatively insoluble salt generally induces a tendency in such salt to crystallize out, and so become a source of pinholes in the negative. Permanganate of silver is formed in the shape of fine needle-shaped crystals of a bronze colour when strong solutions of nitrate of silver and permanganate of potash are mixed. We have heard of one case in which pinholes followed the addition of permanganate of potash to a bath; and this, there is little doubt, was due to formation of the minute crystals in question. Dilution and filtration of the solution effected a cure.

We remarked, above, that the injurious portion of the organic matter present in a bath would be first removed by the action of a permanganate. This may require explaining to some of our readers. The ether and alcohol which accumulate in a nitrate bath are comparatively, if not entirely, innocuous whilst they remain in the bath without change; but they generally give rise to the formation of aldehyde and similar bodies, which have reducing action on salts of silver, and so induce fog; and it is with these substances that the first reaction of the permanganate will take place, and if only sufficient be added to effect their oxidation the tendency to fog will be removed, and no further change effected.

The following letter, one of several recording successful results which we have received, suggests one or two further comments which may be useful:—

"DEAR SIR,—I have experimented with the permanganate of potash, as suggested by Mr. Johnson and yourself in last Friday's NEWS.

"I had about 60 ounces of very old bath, which I was awaiting an opportunity of boiling down, having tried nearly all other known remedies—such as rendering neutral and sunning, adding cyanide and sunning, boiling, &c.—but to no permanent use.

"I procured the dark purple crystals, and dissolved 20 grains in one ounce of distilled water, and added the whole to my bath gradually, shaking well between each addition. The solution rapidly assumed the colour of clay, very difficult to see how things were going on. So I determined to filter, and, finding it still smell very strong of alcohol, or old rum, I determined to add, gradually (the colour of the bath again becoming very dense), until all smell had disappeared, which required 30 grains more in 1½ ounces of water; again filtered. The deposit this time was of a very deep chocolate colour. I then weighed with the meter, and found it had dropped from 40 to 36 grains; and being slightly acid to litmus paper, I neutralized with a 10-grain solution of caustic potassa, and then added a few drops of dilute nitric acid. I then tried a plate, and found it a complete success; how long it will remain so has to be tried. I enclose you two prints from negatives taken before and after doctoring; the difference will be apparent without marking.—Yours respectfully,

M. DUBONT.

"Carlisle, February 26, 1868."

We may remark, at the outset, that the prints enclosed show very satisfactorily the improvement which had been effected by the treatment employed. But it seems evident from the description that an unnecessary excess of the permanganate had been employed, too little time being allowed for the reactions to be completed before adding more of the permanganate. A 20-grain solution has generally been recommended; but we should recommend for general use among photographers a still more dilute solution: one containing 10 grains to the ounce will probably answer every purpose. The bath to be treated should be turned out into a beaker or bottle, and a small portion—say a drachm—of a 10-grain solution to a pint of nitrate bath added, the solution being then agitated. If the pink colour rapidly disappear, a little more may be cautiously added; and when a faint tinge of the pink or purple colour remains, the solution should be set aside for a few hours to allow the reaction time for completion. It is not necessary to go on adding permanganate until all trace of the smell of alcohol is removed, as a portion of that body may be present without producing injurious results. The "chocolate-coloured deposit" would be binocide of manganese, and, probably, a little permanganate of silver, as the bath is described as being reduced in strength. It should be remembered, however, that the strength of a solution as ascertained by its specific gravity is not very accurately indicated after treatment of this kind.

We hope shortly to lay before our readers the result of some experiments with permanganic acid, by which we believe all the advantages of the potash salt may be secured, and, at the same time, immunity from some of the possibilities which we have indicated.

In a former article we suggested that permanganate of potash might be found useful for oxidizing the final traces of hyposulphite in silver prints. Experiment shows, however, that its action cannot be rendered available, the prints becoming discoloured by its action. The albumen decomposes the permanganate, and itself becomes stained with the brown tint of the binocide of manganese formed.

### THE CARBON PROCESS, NOT BRAUN'S.

We had occasion, some little time ago, to correct a statement by the Abbe Moigno, in which he spoke of the carbon process so successfully worked by M. Braun, of Dornach, as the discovery of that gentleman. As error has frequently a singular vitality, we again feel it our duty to correct a similar error, repeated with much circumstance, by our English contemporary the *Athenæum*, as such a statement by a journal of considerable influence is likely, if uncontradicted, to carry weight, and might possibly be hereafter quoted as evidence. In a recent notice of the admirable reproductions of M. Braun, now exhibiting at Leggatt's Gallery, in Conduit Street, and at Colnaghi's, in Pall Mall, our contemporary says:—

Some few years since it was announced that M. Adolphe Braun, of Dornach, a French subject, had devised a method of reproducing the admirable results of photography with perfect success, and, what was of hardly less importance, unchallengeable permanence. Also, it was stated that the artistic world was to have the benefit of this method by its being employed to copy, in complete fidelity, drawings by the old masters, and of their pictures, such as broad or monochromatic treatment offered fairly to the chemicals of the camera. This desirable method is styled the carbon process. Photography had long before done all, or nearly all, that was to be desired in transcribing faithfully, but beyond that nobody trusted the salts of silver, which, protean as they are before the light, and affected by time, too often left of a costly and exquisite reproduction nothing better than a sere and spotty waste of paper. Folks wondered why these unfading transcripts of photographic copies—improved upon ordinary photography as they are—were not brought to England in larger numbers than private hands could bear. Here, at last, they are to be deeply enjoyable, and purchasable cheaply with wealth and amplitude of choice from half the famous cabinets of Europe. Messrs. Colnaghi, of Pall Mall East, and Messrs. Hayward and Leggatt, of Cornhill, have hung the walls of large rooms with copies so exact, that it would be next to impossible to decide between them and the originals; and in such numbers, that almost all the great masters are displayed, as it were, by their first thoughts and swiftest workings at home, before the models supplied the bare and crude materials for art in the grandest pictures. What may be bought for a few shillings must be shown by noting the prominent items out of a gathering which is so very great and rich in beauty and associations that it would supply the means of amplest satisfaction to the best-stored minds—a whole education to the tyro and the amateur.

A facsimile—imperishable, as the men of science say, and perfect, as we know—of Michael Angelo's original study for maternal "Night," on the Medicean tomb at Florence, may be had for 7s. 6d. It is a drawing preserved in the Louvre, in Italian chalk, on paper that is now grey.

We have not space to follow our contemporary through an admirable criticism of this and the other works produced in carbon, which concludes by a statement that the drawings in the British Museum are in course of reproduction by the same process. Our duty here is simply to repeat what we have before stated, that the process used by M. Braun is solely and in every detail that of our countryman, Mr. J. W. Swan, of Newcastle-on-Tyne, whose French patent was purchased by M. Braun, who now most successfully carries out the instructions and arrangements which Mr. Swan visited Dornach to introduce. We are glad to be able to state that there is every probability that the valuable drawings of the British Museum will be reproduced by this perfect and permanent mode of securing facsimiles. We shall shortly be able to announce more precise details of this project.

### VISITS TO NOTEWORTHY STUDIOS.

#### MR. SARONY'S STUDIO AT SCARBOROUGH.

We shall next ask our readers to accompany us to one of the largest and handsomest establishments devoted to photographic portraiture in this country: we probably risk no error if we say in the world. Metropolitan photographic establishments in which considerable business is done are often very much limited in extent and convenience by the exigencies of position; whilst ordinary provincial establishments are generally bounded by the limited requirements of the business; but a first-class fashionable watering-place, with opportunities equal to those of London for the creation of a lucrative business, generally offers at the same time unlimited facilities for building and organizing an establishment as complete and comprehensive as the largest business requirements or the boldest enterprise may demand; and hence it happens that, in such places, some of the noblest buildings devoted to photography are to be found.

Mr. Sarony's establishment is probably the most extensive of the class. It is a magnificent building in the middle of a square of handsome residences. If it had been of Gothic instead of Italian elevation, it might easily have been mistaken for a church. As it is, the first impression is that it is a Town Hall or some other public institution. The building itself is 153 feet by 66 feet, and is surrounded by a garden consisting of ornamental lawn and shrubs, the extent of which is 240 feet by 180 feet. Ascending a broad flight of steps, and entering a spacious vestibule, a series of reception-rooms on either hand are seen, each devoted to a certain class of specimens, for every style of picture produced in the establishment has its own apartment, where it may be displayed to advantage without being killed by the presence of another style of work. Artists know well that oil paintings and water-colour drawings hanging in juxtaposition mutually injure each other; the water colours appear to lack force by contrast with the oil paintings, and the latter seem to lose delicacy and purity in the presence of water colours. Here, then, each class—plain photographs, photo-crayons, porcelain pictures, water-coloured photographs, and oil paintings—has its appropriate gallery, where its qualities may be fairly examined under fair conditions.

Ascending the broad flight of stairs leading from the vestibule, we enter the largest of these reception-rooms, described as the drawing-room—for we may remark that every room in the house has its name and purpose inscribed in gilt letters above the door. The drawing-room is a magnificently decorated and handsomely furnished apartment, 50 feet long by 33 feet wide. The decorations of the room are in exceedingly fine taste, and, although extremely gorgeous, the *tout ensemble* is quiet and harmonious. Without entering into details of description, it may enable the reader to form some conception of the character of the room if we state that we understand that about two thousand pounds were expended upon its complete equipment. On easels, on tables, &c., fine examples of water-coloured portraits are scattered about this room, which is, we understand, during the season, generally crowded with fashionable visitors.

Our readers would risk some bewilderment if we were to ask them to accompany us through the 59 rooms into which the building is divided; 33 of which will be devoted to business during the coming season, 21 rooms, the number hitherto used, having been found insufficient. Ascending from the drawing-room and passing various dressing-rooms, painting rooms, enlarging rooms, and rooms devoted to different branches of the business, we reach the studio or glass room, which we are agreeably surprised to find is not uselessly large: it is just large enough for perfect efficiency, but not so large, as in some cases we have seen, as to sacrifice efficiency to appearance.

The studio permits the most rapid working of almost any that we have ever seen: the exposures in our presence in the month of January averaging from five to seven seconds

with a Dallmeyer's No. 2 B lens and the second or third stop. In summer the exposures must be nearly instantaneous. The total length of the studio is 27 feet; its working width does not exceed 10 or 12 feet, although more space could be included if required. Of the length, 10 feet at the end, where the camera stands, are quite unlighted, something in the nature of a tunnel. The side-light, which faces north, is 14 feet long and 9 feet high; the top-light—the form of the room being that of the penthouse or lean-to—is 14 feet long by 8 feet broad, both top and side-light being clear glass. A small portion of high front light can be used, which is placed at the point where the tunnel commences; it is usually, however, covered with blinds. About 3 feet at the end where the sitter is placed are opaque side and top; a white calico blind at the top, over the head of the sitter, is the chief blind used; a white blind for reflecting light on the shadowed side is at times used, where the character of the head or the effect desired renders it necessary. In summer, direct sunlight is prevented from entering any part of the studio by narrow blinds placed on frames outside. Mr. Sarony contemplates stippling the whole or part of the skylight in imitation of ground glass, so as to subdue the top-light a little, making the side-light the dominant light. With the present arrangement, however, the results produced are very fine, bold, delicate, and well-modelled.

Mr. Sarony always, in producing card negatives, works on a plate 12 by 9½ inches. Upon this plate eight distinct portraits are taken, consisting at times of as many different positions of one person, or of the portraits of several persons. Usually each plate contains the portraits of at least two persons, and sometimes of four. The camera is provided with one lens, and a repeating back giving eight single exposures. At first glance this mode of working seems to involve several difficulties: there is the danger of the plate drying and producing stains, from the length of time which must elapse when eight distinct exposures, with varied arrangements, are given between the excitement and development of the plate; and there is the still more serious difficulty of uniform printing from images of possibly unequal density; and the further difficulty of some portraits on the plate having occasionally to be rejected. Notwithstanding this, Mr. Sarony regards the mode of working as economical and convenient. To make it so, it is evident, however, that two important qualifications in the photographer are imperatively necessary: we mean rapidity and certainty in operating. These Mr. Sarony possesses in an essential degree. In the negatives we saw, a singular uniformity of excellence and of printing qualities prevailed, and whether they contained one, two, or four persons, as a rule all seemed good, although it is quite certain that at times some of the portraits on a plate must be rejected. In rapidity of posing and arrangement, and in securing variety, grace, freshness, and spirit, in his poses, we have rarely seen Mr. Sarony's rival. In one case, of which we especially noted the time, a lady received eight different exposures on one plate, some sitting, some standing, and all graceful; the operation was completed in ten minutes.

It must not be forgotten, however, that for much of this rapidity in securing varied poses, important facilities are given by Mr. Sarony's patent posing apparatus, or head and body rest, which we noticed some time ago; which, by the readiness with which it is adapted to almost any position, materially aids the clever artist in rapidly and efficiently carrying out his arrangements; and that the security and support it gives the sitter materially lessens the waste of time and spoiling of plates which would otherwise occur from moving.

The most important part of the work in the establishment consists in the production of enlargements for colouring in different modes; and the facilities for effecting this work are exceedingly complete for working either with sunlight or the oxyhydrogen light, a Monekhoven's apparatus being used for the former. In some cases, in working on canvas, a

developing process is used, but recently Mr. Sarony has chiefly used the carbon process in securing a basis for important paintings. Mr. Sarony has, we understand, secured the sole patent of Mr. Swan's process for Scarborough, and intends next season to prosecute it with vigour. A steam-engine of two-horse power was in course of erection during our visit; it is intended for aiding in making and drying the carbon tissue.

A spirit of active enterprise, in which no effort of any kind which may conduce to the excellence of results or to the convenience of sitters is spared, seems to govern the establishment. Fixed at one end of the studio, and ready for use in a moment, is a copying camera in which transparencies can be produced from a negative as soon as it is taken; the transparencies placed in the huge magic lantern or enlarging apparatus with the oxyhydrogen light, and projected on the screen amplified in such degree as may be required to enable the sitter to form a very perfect idea of the finished effect of the enlarged picture from any one of the negatives taken, and permit a ready and certain selection from the choice presented. This is one mode in which the convenience and satisfaction of the sitter are consulted and expansion of business promoted. Another, recently introduced, is the production of a cabinet negative of each sitter requiring a card. The camera, with a plate taking four cabinets, and repeating back, is placed just behind and to one side of the card camera, the exposures being simultaneous. At the completion of the actual order the cabinet prints are shown, and, of course, many sitters are pleased to obtain excellent portraits in such a satisfactory size and style without additional trouble.

The coloured work possesses a degree of excellence rarely attained in painted photographic portraits, artists of the highest skill being employed in each department of the work. During the season a large number of artists are employed, some of them being retained throughout the year, the best work requiring skill, and time being inevitably in arrears at the end of each season. An excellent illustration is here afforded of the influence of photography on the profession of the miniature painter, which at one time it was alleged to have ruined. Several of the best artists in this establishment earn each from five to six hundred pounds per annum. On one occasion Mr. Sarony made an arrangement with a miniature painter of reputation to colour his work, guaranteeing him a thousand pounds per annum; the amount the artist actually received for work done in a year was considerably more than that sum. In the colouring of the portraits in Mr. Sarony's establishment the principle of division of labour is usefully carried out, some artists being engaged on flesh and some on draperies. For instance, in the portraits finished in water colours, the draperies and backgrounds are all painted by an artist of high reputation, whose portraits are familiarly known in the once popular and fashionable Books of Beauty which were annually published; they then pass into the hands of a gentleman with rare skill in painting heads, to be finished.

We have referred to the use of carbon printing as a basis for the oil painting; but if the finishing of any photographic portrait render it independent for permanency upon the process by which it is produced, it should be so here. The enlarged image having been duly produced by the photographer, the canvas passes into the hands of an artist, who works on it in black and white, producing an admirably finished portrait in monochrome; and as this is all solid colour the portrait must remain, even if the photographic image fades. After this treatment it passes into the hands of the artist, who finishes it in colour. The portraits of this class of work, which we saw, by the chief artist in this department, were admirable examples of oil painting, equalling the majority of the portraits which we find in each year's Royal Academy Exhibition, and surpassing some. There was a gratifying absence of the hard, crude, raw, opaque effect too common in oil-coloured photographs. The flesh painting was solid and firm, healthy and pleasant in colour, a luminous

and transparent effect pervading the whole picture. The prices for this class of portraits, we are glad to add, are commensurate with the work, ranging from twenty to a hundred guineas.

We should simply confuse our readers, without edifying them, if we were to ask them to accompany us through every room, devoted, from garret to basement, to portraiture, in this large establishment. It is throughout a noble monument of photographic enterprise, the creation of individual skill and energy. Few men have more daring and energy than Mr. Sarony, few more readiness or versatility in resource, few more aptitude in seizing occasion and manipulating circumstance to business ends, and these are all elements in securing a great success; but underlying all this, and forming a solid basis for the connection gained by business tact, is a thoroughly fine artistic taste, and a rare degree of photographic skill, the result of natural aptness, and the practical experience of more than a quarter of a century spent exclusively in photographic portraiture. Mr. Sarony commenced the photographic profession as a Daguerreotypist in Canada, in 1842, and has practised it in this country, in its various phases, since 1844. His career has been a singular and adventurous one, full of interesting and instructive episodes, which we may one day detail. Not the least gratifying of these incidents is recalled to our memory by the sight of two silver medals, one from the Board of Trade, and one from the Royal Humane Society, for "saving life." The incident is probably fresh in the minds of our readers, when, a few years ago, during a memorable and terrible storm, Mr. Sarony plunged into the boiling surf to save the lives of men from a vessel broken to pieces on the Scarborough rocks, and how he brought to shore the body of his companion in the heroic work, Lord Alfred Beauchere, whose life was beaten out of him by the turbulent waters.

We have visited Mr. Sarony's studio in winter, and obtained a brief glance at its capacity and arrangements; we shall probably revisit it again in the season, and ask our readers to accompany us further through its varied and suggestive departments.

## ECHOES OF THE MONTH.

BY AN OLD PHOTOGRAPHER.

PHOTOGRAPHIC PIRACY—MR. McLACHLAN'S DISCOVERY—EXHIBITION OF PHOTOGRAPHS—BRAINS IN PHOTOGRAPHY—THE DISCOVERY OF THE CARBON PROCESS—"PUNCH" AND "FUN" ON PHOTOGRAPHY—THE PHOTOGRAPHIC SOCIETY OF LONDON—THE SOCIETIES.

I HAVE often been puzzled by observing that certain forms of crime or misdemeanour are regarded by society, or some portions of it, with a very lenient eye; and it is generally, moreover, to a class of crimes which, in a high code of morality, would be regarded as without palliation, that this gentle consideration is given. A tradesman is, for instance, in the constant habit of giving short weight, and defrauding the poor of five or ten per cent. of the small pittance which is to keep body and soul together. After having continued this practice for years, and acquired by it many hundreds of pounds, he is perhaps convicted, and, after paying a trivial fine, again proceeds on the even tenor of his way, not scouted from society, not branded, not ruined. So if, instead of giving short weight, he adulterates his goods, he may generally escape scot free; whilst the starving wretch who steals a loaf of bread must, if convicted, inevitably bear the taunt for life of having been a gaol-bird.

The reflection is very trite; but I am reminded of it by the recent convictions for piracy at the Guildhall. Piracy has too long been regarded by many with a leniency similar to that extended to adulterations and similar peccadilloes. It has been regarded as something illegal, but scarcely immoral; and if it were managed so as to just escape the law, it was rather clever than blameable. If Mr. Graves, for instance, after spending twenty thousand pounds upon

bringing out an engraving, had the misfortune, through neglect of his own or of any of his people, to issue a single impression not bearing the publication line, the Philistines might be upon him, his plates might be pirated, his outlay wasted, and himself ruined, without obtaining protection from the law, or much sympathy from the public. In most cases where photographs have been so pirated, all kinds of singular impediments have, by authority, been thrown in the way of obtaining redress, and convictions have been difficult to secure.

When, therefore, in two recent cases, Sir R. W. Carden has inflicted fines amounting in the aggregate to £380, it strikes many people with a refreshing sense of justice. The cases, as reported, appeared to be without any defence beyond legal technicalities. I remember some time ago in these columns pointing out that the question of piracy had two sides, and that where proprietors of pictures had, for purposes of their own, voluntarily resigned the protection of the law by neglecting to comply with the conditions upon which the law gave them a secure property in their ideas, they ought not to complain that these ideas become the common property of the public. In these cases, however, the convictions were obtained for the piracy of clearly defined property, for which every pains had been taken to secure the protection of the law; and few people will, we apprehend, be sorry that a severe penalty has been enforced. I hope that, for the credit of the art, the recent cases will serve as a terror to evil-doers for some time to come.

I glean from your recent remarks on Mr. McLachlan's discovery that my formerly expressed idea that there is really something in it is correct: how much it seems we must wait to learn. But the fact that two gentlemen like Mr. Spiller and Mr. Le Neve Foster, after having listened to the statement, required to verify it by experiment, suggests that they were neither in a position to exclaim "Bureka!" nor "Moonshine!" That, at least, is the deduction I draw from the slender premises yet accessible.

There have been two or three exhibitions of photographs open in London lately, which those of your readers who have opportunity would do well to visit. A fine collection of carbon prints by Braun, chiefly of reproductions, is exhibited at Leggatt's Gallery in Cornhill, and a similar collection at Colnaghi's. There is also an exhibition of Mrs. Cameron's pictures at the German Gallery in Bond Street, the photographs at which have won many favourable opinions from the art critics. There is something rather amusing in the mode in which this praise is bestowed: in some cases with something like an apology, on the ground that they are so little like photographs. The *Athenæum* is rather perplexing, for whilst "warmly commending" them to the "general student and artist," it remarks, in reference to those of them who "aim at that which is properly brain-work, the less said about them the better for all parties." Now, since the sole merit possessed by Mrs. Cameron's photographs belongs solely to the brain-work put into them, and is due not to mechanical, chemical, or manipulatory excellence, nor to technical superiority of any kind, but is solely the result of the artistic feeling and artistic treatment which give them a value in spite of technical shortcomings, it is odd enough, surely, to condemn the brain-work and praise the results. This is, however, mere inconsistency; but the same journal, referring to the exhibitions of carbon prints, announces the process, with much circumstance, to be the discovery of M. Braun. After the publicity which has been so repeatedly given to the fact that the discovery of carbon printing as a practical process is due to an Englishman, and that it only belongs to M. Braun by purchase from Mr. Swan, it is surely something more than inconsistent merely, or careless, in a journal like the *Athenæum*, to gravely make such an announcement.

It seems that *Punch* thinks the old idea of taxing photographs worth reviving. A penny stamp is such a small tax on each picture that no one would object to pay it, *Punch* thinks. But unfortunately, it would not, I fear,

come out of the pockets of the purchasers. The normal price at present of a card portrait is one shilling, and it would be very difficult to induce the public to pay 1s. 1d. The photographer would have to bear the brunt, and it would simply amount to an average impost of 8 per cent. upon the total amount of business done by photographers generally. If the principle were carried out and applied to all trades, it would certainly render an income tax unnecessary; and if applied to photography, there could be no reason why other industries should not be similarly taxed.

I see that *Fun* also has been interesting himself in photography, and has evidently been reading your pages, for he contrived to have a laugh at one of your correspondents. What a pity that he should first misquote, and then laugh at the blunders he himself has made. Scarcely worthy of *Fun*, this! It is possible to wear the cap and bells, and yet be accurate in such a little matter as a quotation.

I am glad to see that the Photographic Society of London commences this year with a prospect of greater success and prosperity than it has possessed for some time. It has been not a little amusing to hear the charges of mismanagement, especially of a financial kind, which have from time to time been brought against it during the last few years, chiefly by those who never contributed a shilling to its funds, and who therefore could have no legitimate concern in their expenditure. It has, however, been generally understood for some time past that the finances of the Society were at low water; and seeing that the whispered statement has generally been accompanied by an intimation that it had at one time possessed funded property, which, like a spendthrift, it had got through in some unknown manner, your recent explanation of the way the money has gone has, to my knowledge, done good service, and satisfied many worthy persons. Only one or two of the large items referred to seem to have been for objects which could not advance the art, and one of these is of a nature which should silence cavilling on the score of expenses in one quarter, at least.

The annual meeting promised well for the interest of the coming year. Mr. Johnson's suggestion for rectifying old baths has been employed successfully in more than one instance coming within my knowledge. Why was permanganate of silver, as proposed by Mr. Crookes, not more generally tried? I presume, because the salt was not found generally in commerce. Mr. Solomon's production of a fine enlargement in half a minute by the magnesium light seemed to take everybody by surprise, but left no doubt about the success. The interesting photographic experiences of Dr. Mann in tropical climates, the new phase of landscape photography by Mr. Johnson, and the photo-lithographic and photo-engraving experience of Mr. Griggs, which are promised in meetings yet to come, must give great interest to the proceedings; and such anticipations must help to maintain and increase the vitality of the Society.

The paper read at the North London Society, on glass for photographic purposes, should, and doubtless will, attract an amount of attention to a neglected subject which it is surprising it has not hitherto received. The possibilities of change of colour in glass are unfortunately beyond the control of the photographer; but an occasional examination of a broken pane is easily made, and it would well repay a portraitist to have his glass room re-glazed now and then, if he could, by doing so, shorten his exposures by one-half. In any case, it should call attention to the importance of occasional thorough cleansing. At the South, Mr. Taylor's suggestion for the use of safety-valves in gas bags, and Mr. Fry's *Omnium Gatherum*, were capital papers. At the Edinburgh Society, Mr. Davies read a paper on a desirable improvement in mounting view lenses. Some of M. Salomon's portraits were exhibited, and elicited some judicious remarks on their beauty from the Secretary; and a commendable protest from Mr. Davies against the Vandalism of a proposal to destroy one of the pictures in order to ascertain if it were

touched, as he was not aware that any disavowal of the aid of the pencil had ever been made by M. Salomon; nor, he might have added, I think, by any one else for him. One gentleman held a different opinion as to their beauty, and thought that many of them were such as hardly any true artist could have perpetrated. I hope that after such a verdict, M. Salomon will feel sufficiently ashamed of his work. At the Manchester Society, Mr. Nolon read a paper on apparatus and Materials for the production of oxygen. The annual soirée of this society was a success. An eloquent and exhaustive address by Mr. Green, President of the Bradford Society, at a recent meeting, well repays perusal. Several of the provincial societies seem to have fallen into abeyance, but those still in a state of activity seem, from the papers and discussions, to be in a healthy condition.

## PICTORIAL EFFECT IN PHOTOGRAPHY;

BEING LESSONS IN

COMPOSITION AND CHIAROSCURA FOR PHOTOGRAPHERS.

BY H. P. ROBINSON.

### CHAPTER VI.

"In the fine arts that composition is most excellent in which the different parts most fully unite in the production of one unmingled emotion, and that taste the most perfect where the perception of this relation of objects, in point of expression, is most delicate and precise."—*Alison*.

"The unlearned eye first admires painting as an art of imitation; it is only from the progress of our sensibility and the practical cultivation of our minds that we begin to comprehend the greater compositions of genius, after which the unity of expression is felt to be the great secret of the power of painting."—*Sir Thomas D. Lauder*.

"The great object of composition being always to secure unity—that is, to make out of many things one whole—the first mode in which this can be effected is by determining that one feature shall be more important than all the rest, and that the others shall group with it in subordinate positions."—*Ruskin*.

### UNITY.

In my first chapter I spoke of unity as one of the essential constituents of a successful picture. In some respects it would have been better to have considered what was meant by unity in that place, but it would have delayed me in placing before the student the law of balance and contrast in which I was anxious to secure his interest at the outset.

In speaking of unity as one of the essential elements of composition, I did so from a firm conviction that whatever beauties a picture may contain, however exact its imitation of nature, correct its arrangement of lines, beautiful its colour, extreme its finish, or great the dexterity of handling manifested, no perfect sense of satisfaction will be conveyed to the eye if the lights are scattered, if breadth of light and shade be not preserved, or if two or more episodes, unconnected with each other, appear on the same canvas.

Unity has been well defined as "the keystone of nature, and expresses the harmony of the Divine mind as rendered in creation." Unity can only be attained by a study of first principles. It is the law of nature that principle shall precede details; in the account of the creation of the world the general design is described as first laid down, and the details as following. Unity is so simple that it is often overlooked; but no success in any other qualities desirable in a picture, as I have already said, will compensate for its absence. In photographs, where there is no colour to distract the attention from the design, it is especially necessary. It is the absence of unity in the arrangement of the figures in a photographic landscape that so often mars the beauty of an otherwise effective picture. It is too often the practice to scatter figures, dressed inharmoniously with the scene, over the foreground of a landscape, without any reference to one another or the propriety of their being there at all, and so unity is disregarded and lost.

Like most of the elements which constitute a good picture, unity is a quality more easy to feel than describe; but I think I shall not be far wrong if I define it as the fit connection of all parts to a perfect whole. The province or function of unity is to combine and bring to a focus the secondary qualities, such as variety, contrast, symmetry, &c.

It is equally opposed to scattered ideas, scattered lines, or scattered lights in a picture. In nature, light, when broken in its passage, though the amount be diminished, is rendered more irritating to the eye. We can bear the full, uninterrupted splendour of the setting sun, but when its rays are cut up and divided by passing through a screen of leaves and branches, the irritation affects the least educated eye. This feeling of irritation, caused by spotty lights, more properly belongs to the subject of light and shade, and will be spoken of in its proper place further on; but there is a unity of lines and a unity of action that must be considered, more especially in the composition of figures; but unity of purpose is as necessary in the expression of a landscape as unity of action is in the figure-subject. All objects must assimilate in one point, however dissimilar they may be in others. There must be some conformity of tone and relation of line, however great the variety in the leading characteristics of the view.

In photographing any object, whether landscape, portrait, or group of figures, one leading idea must be maintained. The fact that has to be stated must not be clouded with confusion. The work should constitute one whole, it should fully pronounce its own meaning, there should be nothing left for verbal explanation. A picture should not require a showman; a picture that does not tell its own story is as tiresome as a volume overlaid at all parts with notes and annotations to explain that which should need no explanation. In a landscape will always be found some object of more importance than the rest, to which all other parts are subordinate, and to which all other objects lead; it will be the duty of the photographer to choose such a position for his camera as will increase this effect, so as to make the most of the principal object, or the subject of the picture, and to allow no rival to be near to detract from the full effect. A very common instance of the loss of unity in photographic landscapes is in the position and action in which figures are placed. I have an example in my portfolio, a description of which will illustrate how much mischief may be done by this disregard of unity.

The scene is a rural lane crossed by a brook, and closed in with trees. Halfway down the lane, growing on the flower-covered bank, is seen the trunk and gnarled roots of a grand old oak, which receives the principal light, which is repeated in the water, and gradually diffused through the picture. Stretching from the left are the dark and graceful branches of a sycamore tree, which, extending partly over the trunk of the oak, by the opposition of their dark leaves in shadow, increase the brilliancy of the chief mass of light, and assist in leading the eye to the principal object. There is no mass of light so large or so high in tone as that on and around the tree trunk—not a line out of place; and it is altogether one of those scenes on which the eye loves to linger, and which can be quite expressed by photography. And yet this is one of the most irritating pictures I ever saw. The cause of the irritation is supplied by comparatively a very small part of the whole; but it is there so palpably, that I keep the picture only as a warning, and never look upon it for pleasure. In the centre of the picture, cut out sharply against the light, looking straight into the camera, having no part in, and, apparently, caring nothing for the lovely scenery around, is this figure. And thus one of the most beautiful photographs I know is spoiled by this ridiculous incongruity, which destroys all unity. If two or three village children had been introduced, naturally engaged picking flowers from the bank, they would have appeared like a rich cluster of jewels in an appropriate setting.

The same remarks apply equally to portraits or groups, of which more in the proper place; as the subject will receive fuller treatment in the section devoted to light and shade.

In this chapter I direct attention to a principle rather than to mere rules, which can be expressed in so many words. But

I must impress thus early upon the student this dominant idea; that if a picture is to be successful, it must have a oneness of purpose, a oneness of story, a oneness of thought, a oneness of lines, a oneness of light and shade. Everything must have a meaning, and the meaning must be the object of the picture; there must be nothing "to let."

I am the more desirous the student should "feel" what unity is, because unity and balance together constitute the chief mechanical elements of pictorial effect, and may exist altogether apart from any story to be told or intention to be expressed in a picture, although the telling of a story rightly is a part of unity, which seems paradoxical. These two, balance and unity, should therefore be thoroughly understood first, and other elements of harmony, such as refer to intention, subordination, keeping, &c., are not the less important, but will always be all the more perfectly understood and expressed after the student has thoroughly grounded himself in the more mechanical elements; as, however prolific a man may be in ideas, he cannot express these ideas intelligibly until he has learned a language and its grammar, or laws of construction. Balance and unity are principles of construction, upon which must be based every intention to be expressed in the picture. I lay the greater stress upon this initial idea, because it has too often happened that the art-teaching which has been supplied to photographers has dealt rather with the thoughts to be expressed than on the modes of expressing them; and it is of little use endeavouring to teach a man to write poetry until he has learned to spell.

#### PRINTING BY DEVELOPMENT.\*

During the winter months, when daylight is weak and dull, and there is little of it, the process of printing by development offers a useful and precious resource available for the production of prints. The process, which is likewise very suitable of application in producing enlargements by means of the solar camera, is similar in its manipulations to the ordinary collodion process, where the image is obtained by the aid of a reducing agent; and the materials employed in both cases are almost identical.

##### FIRST METHOD WITH CHLORIDES.

##### Salt ing Bath.

Chloride of sodium (common salt) ...	65 grammes
Hydrochloric acid ... ..	6 drops
Rain water ... ..	375 cub. cents.

The paper is immersed in this bath, and allowed to remain therein for two or three hours, after which it is taken out and dried.

##### Sensitizing Bath.

Nitrate of silver ... ..	30 cub. cents.
Citric acid ... ..	5 grammes
Rain or distilled water ... ..	250 cub. cents.

The paper is floated on the bath for three minutes, and is then drained and suspended on clips, care being taken to remove any accumulation of liquid at the edges or in the corners. As soon as the paper is nearly dry, it is exposed to light under a negative or upon the screen in the solar camera, until the appearance of a faint image is observed. With a negative exposed to direct sunlight, the duration of this operation should never exceed three or four seconds; in bad weather a minute, or even more, will be necessary. When the impression is sufficiently distinct, the paper is withdrawn from the frame, and placed, face uppermost, upon a glass plate somewhat smaller in size than the sensitized sheet; the top and bottom edges of the paper are then folded under the glass, and the whole placed at the bottom of a large gutta-percha developing dish.

\* *Moniteur de la Photographie.*

*Developer.*

Pyrogallic acid	...	...	8 grammes
Citric acid	...	...	4 "
Water	...	...	190 cub. cents.

A quantity of the developer, sufficient to cover the paper, is then poured into the bath, which is then tilted a little on one side; by a steady movement the solution is then made to flow smoothly over the surface of the print in such a manner as to prevent the formation of ripples or back-flowing of the liquid. This is a very important point in the manipulation, for the slightest unevenness of flow in the developer will produce the same injurious effect upon the print as it would upon a collodion plate. The development is very soon accomplished, as rapidly as with the wet collodion process, and demands the same amount of care and vigilance. When the operation is judged to have gone sufficiently far, the developer is drawn off by means of a tube fitted to the bottom of the bath, and the print is then carefully washed by means of a rose. It is fixed with the following solution:—

*Fixing Bath.*

Hypo sulphite of soda	...	...	30 grammes
Water	...	...	500 cub. cents.

The prints are immersed in the fixing liquid, and allowed to remain there until the whites have attained the requisite purity; this requires an interval of from ten minutes to half an hour, and when properly fixed, the prints are finally well washed to remove all traces of hyposulphite.

## SECOND METHOD WITH ALBUMEN.

*Salting Bath.*

White of egg	...	...	310 cub. cents.
Distilled water	...	...	470 "
Chloride of sodium	...	...	4 grammes
Bromide	...	...	4 "

The salts are dissolved in the distilled water, and the albumen then added to the solution; the white of egg should be beaten up to a froth, and allowed to stand in a cool place for several hours, when the clear liquid is carefully decanted or filtered off and added to the salting bath.

The paper is floated upon the bath in the ordinary manner for about three minutes, and then suspended by wooden clips to dry. When dry it is placed in a long metal box, and plunged into a deep saucepan, full of boiling water, care being taken that the water does not touch the paper, but that the whole surface of the latter is subjected to the temperature of the steam. This operation, which is instituted for the purpose of coagulating the albumen, will be more successful if the hot steam is allowed to come into contact with the albuminized surface; but at the same time this part of the process is not absolutely necessary, as the coagulation may always be effected in the sensitizing bath.

*Sensitizing Bath.*

Nitrate of silver	...	...	30 cub. cents.
Distilled water	...	...	375 "
Citric acid	...	...	12 grammes
Alcohol	...	...	30 cub. cents.

The paper is sensitized, and dried in the ordinary manner. An exposure of eight to ten seconds will suffice in the sunshine, but a period of several minutes is necessary in a weak or diffused light. It is only when the image has become perfectly visible that the exposure can be deemed to have been sufficiently long.

*Developer.*

Galic acid	...	...	3 grammes
Distilled water	...	...	60 cub. cents.

The operation of developing is best conducted in a gutta-percha or glass bath. The print is first slightly moistened in order to make it adhere to the bottom of the bath, and the latter being tilted, the developer is poured in, and then made to flow evenly over the surface of the paper; care must be taken that the liquid covers the whole surface uniformly. If the exposure has been nicely regulated, the development of

the image is brought about very rapidly, at the end of two or three minutes; in cold weather the operation may be accelerated by employing a somewhat stronger developer, or by slightly warming the solution. The gallic acid, when dissolved, possesses a strong tendency to become mildewed, and a small piece of camphor or a drop of essence of clove should, therefore, be added to the solution to prevent the arrival of such an occurrence. An under-exposed print is very slowly developed, and the prolonged action of the acid imparts a dark, uniform colour to it, weakening all the half tones; on the other hand, an over-exposed print becomes rapidly developed, and must be promptly removed from the developing bath to prevent the whites becoming covered. The best prints are those in which the gradation is very regular, and the impression is somewhat weaker than in the finished photograph. The prints are washed and fixed in a bath containing—

Hypo sulphite of soda	...	...	30 cub. cents.
Water	...	...	625 "

The pictures remain in the fixing bath for a quarter of an hour, and are again washed. If the aspect of the prints does not prove satisfactory after this operation, a gold toning bath may be resorted to, to improve their appearance; any of the well-known formulae may be adopted. If the whites do not appear perfectly clear after development, they may be improved by immersing the prints after they have been well washed in a bath containing 30 grammes of chloride of lime and 300 cub. cents. of water.

## THIRD METHOD WITH AN IODIDE.

*Salting Bath.*

No. 1.—Nitrate of silver	...	...	3·8 grammes
Distilled water	...	...	60 cub. cents.
No. 2.—Iodide of potassium	...	...	27 grammes
Distilled water	...	...	62 cub. cents.

The salts are dissolved separately, and the two solutions afterwards mixed, producing a yellow precipitate of iodide of silver. Sufficient concentrated solution of iodide of potassium is now added to dissolve the whole of the precipitate, and the bath is then in working order. The paper is floated on the liquid in the usual manner for about three minutes, drained, and hung up to dry; it is afterwards floated upon a bath of distilled water, the sheets being placed in pairs back to back, and allowed to remain in the water for several hours, care being taken to turn them over now and then. By this treatment the surface of the paper assumes an uniform pale yellow colour; the sheets are subsequently withdrawn from the bath and dried.

*Sensitizing Bath.*

Distilled water	...	...	800 cub. cents.
Solution of aceto-nitrate of silver	...	...	15 "

This last-named liquid is composed of—

Nitrate of silver	...	...	30 grammes.
Acetic acid	...	...	60 cub. cents.
Distilled water	...	...	300 cub. cents.

If the operator has no wish to provide himself with a supply of aceto-nitrate of silver, he may make use of the following formulae, which is less complicated:—

Distilled water	...	...	800 cub. cents.
Nitrate of silver	...	...	12 grammes.
Acetic acid	...	...	5 cub. cents.

(To be continued.)

## ON CERTAIN PHENOMENA OBSERVED IN THE PHOTOGRAPHIC IMAGE.

BY M. L'ABBE LABORDE.\*

THE last number of the *Bulletin* contains an article by M. Sidebotham, in which that gentleman enumerates the presence in photography of certain curious effects, the causes

\* Read before the French Photographic Society.

of which he is able but imperfectly to explain. My object is to discuss the most common among them, in order to show that in photographs of scientific subjects one should not be too hasty to attribute to the action of light that which may possibly be produced by some other cause.

When two objects, the one white and the other black, are represented in a photograph, touching one another, the contrast is often exaggerated at the points where they meet, the white appearing more white, and the black more black. Many causes may tend to the production of this acknowledged fact; but before looking about for vague and uncertain reasons, let us first see what may be produced by a well-known cause connected with the circumstances under which the developer is used. When the developing agent is poured upon the exposed plate, it encounters a film of nitrate of silver spread equally over the whole surface; as soon as the blacks have appeared, the decomposed nitrate of silver in those parts has yielded up its metal, while on the other portions of the negative, where the light has made but a faint impression, it still remains almost intact. From the parts of the negative upon which it has acted feebly, the nitrate of silver diffuses itself over the adjacent blacks, and re-inforces the margins of those portions; and as it cannot give without losing, the whites bordering upon the blacks thus become more transparent. If the negative is agitated, this action, which is always more energetic wherever the whites and blacks touch one another, is pushed further; it is for this reason that a negative which is moved quickly to and fro during development comes out more rapidly during the first few moments, because the nitrate of silver not decomposed on the whites is made to pass and re-pass over the blacks. All these effects are repeated when nitrate of silver is added to the developer for the purpose of intensifying the negative photographs.

Photographs of the ordinary description do not suffer from these effects, but may even be benefitted by them; but in photographing scientific subjects—as, for instance, in the reproduction of celestial bodies—it is necessary to take these imperfections into account, for we must not attribute to the light that which is due to subsequent causes. The best means of preventing any error in this direction is to develop the image promptly, to wash it immediately afterwards, and, if it requires intensifying, to use an agent which is not quickly redaceable, thus preventing the diffusion of action from the whites to the blacks.

The following solution appears to me well adapted to the purpose, inasmuch as it may be employed in full daylight after the picture has been fixed; its action is very slow, and the density of the negative may be controlled, therefore, with the greatest nicety. It is as follows:—

Perchloride of iron ...	...	...	1 part
Bichromate of potash ...	...	...	3 parts
Water ...	...	...	150 „

The negative should be well washed before the employment of the solution, in order that every trace of the hyposulphite of soda may be eliminated, for if the negative is treated with the solution prior to its being fixed with hyposulphite, the image becomes weakened, and may disappear altogether.

Two films of nitrate of silver may be said to exist upon the latent image: firstly, that which runs freely over the surface after the sensitizing of the plate, and to which the developing agent is added; and, secondly, that with which the iodide is impregnated, and which it is very difficult to remove entirely—a fact demonstrated in certain dry-plate processes, where several washings are insufficient to remove the salt, and it is necessary to employ an agent to remove the last traces of the nitrate. It is this last-named film of nitrate which, conjointly with the developer, produces the picture in the way it has been painted by the light; the free nitrate upon the surface intensifies the image in the manner I have already mentioned. An image washed after development, and exposed to the action of light, assumes the appearance

of a positive, doubtless for the reasons given above, for the nitrate of silver not decomposed, which still impregnates the whites of the picture, has the effect of blackening the same; while the blacks, where the nitrate has already become decomposed, do not undergo any change whatever.

A negative intensified to excess sometimes yields a print in which the whites appear to encroach upon the neighbouring portions, the fine and strongly-lighted lines appearing larger than in nature. Can this effect be attributed to radiation similar to that produced by a bright light upon the organ of vision, or is it due to a lateral diffusion of light? It is possible that the solution of this problem may likewise be found in the subsequent action of the nitrate of silver in conjunction with the developer. In fact, if negatives of this description are carefully examined, it will be found that the blacks appear in relief; but this relief has not been produced only in a vertical direction, and the silver ought to have been deposited laterally, something after the manner in which it is found upon a strip of copper which has been plunged into a solution of silver; whence, therefore, come these blacks upon the negative, which trespass beyond their true limits.

I have observed, in very rare instances, a fact with regard to collodion, which occurred more often at the period when negatives were taken on paper; the whites of the print were bordered by a brown line, which likewise surrounded the blacks. This effect was produced, above all, when I added nitrate of lead or acetate of lime to the gallic acid for the purpose of hastening development, and when the picture thus treated remained untouched for some time. I was of opinion at the time that the deposit formed upon the blacks became slightly diffused, and impregnated the whites; but the regularity of the dark margin, and the circumstance that prolonged washing was incapable of removing the same, seemed to invalidate this explanation. The fact, however, I mention, in order to show once more that we should not be too hasty in attributing to light effects which, in reality, may be produced after the exposure of a negative to its action.

### MORE PHOTOGRAPHIC PIRACY OF ENGRAVINGS.

ANOTHER serious case of photographic piracy was brought before Sir R. W. Carden, on Friday, at Guildhall, in which a conviction in fifty cases was obtained, and fines to the extent of £250 inflicted. The case is thus reported in the daily press:—

Henry Ashford, 3, Queen Street, Cheapside, printseller and photographic dealer, was summoned before Sir R. W. Carden by Mr. Henry Graves, of Pall Mall, publisher and engraver to the Queen, to answer fifty charges of unlawfully selling, on the 6th of February last, thirteen photographs of a painting called "My First Sermon," of the copyright of which Mr. Graves was the proprietor; also of unlawfully selling the following photographs, of which the defendant was not the proprietor, thirteen copies of "My Second Sermon," twelve of "The Railway Station," six of "The Morning before the Battle," and six of "The Evening after the Battle." Mr. George Lewis appeared for Mr. Graves, and Mr. Treherne for the defendant.

John Cattermole said he was in the employ of Mr. H. Graves. From instructions he received he entered into communication with Mr. Ashford. On the 3rd of February he received a letter from him directed to Mr. Clayton, a name he assumed. He had received thirty letters signed Henry Ashford in answer to letters asking for goods, which had been delivered in consequence of those letters. Mr. Ashford acknowledged the receipt of the money.

The correspondence extended over several months. Letters were then put in from witness, signed "John Clayton," ordering goods, and paying money in half notes and Post Office orders, the defendant's answer acknowledging receipt of money on the same date, also a letter dated February 7, 1868, containing the other halves of the notes, and further orders; and the answer to that, stating that the previous orders had been executed.

The witness said he sent a person named King to Southampton, and he brought a parcel. He subsequently sent him to Brighton, and he brought another parcel thence, containing twelve "Railway Station," thirteen of "My First Sermon," and thirteen of "My Second Sermon." He sent £7 4s. to the defendant, the price of six

"Morning before the Battle," and six "Evening after the Battle," but they had not yet been delivered. In assuming the name of J. Clayton he did so for the purpose of detecting the defendant. He had paid between £40 and £50 to the defendant for photographs he had forwarded in order to detect him.

William King (in Mr. Graves's employ) gave confirmatory evidence.

Mr. Henry Graves was then called, and proved the registration of the painting of the "Railway Station." He had never authorised any one to make photographs of his engravings except the one of each made by Mr. Spencer for the purpose of registration. The one plate of the "Railway Station" had cost him upwards of £25,000. The photographs were taken from his engraving. The charge for the engraving was £10 10s., and the photographs could be produced for 9d. by the maker. Mr. Graves proved the registration of the other engravings. He purchased the "First" and "Second Sermon" for £1,700. In consequence of the piracy he had not got back the money the paintings and engravings had cost him. He had never made and sold photographs of his engravings. The photographs were newly made. The publisher's line was on the photographs, showing that it was made since the plate was published. The photographs had even pirated the "trade mark."

Mr. Treherne called Thomas Ashford, brother of the defendant, who said he had been in partnership with him up to last year. He now carried on business at Newgate Street. He knew nothing of Cattermole or Clayton, and never heard of them while he was in partnership with his brother. A letter produced February 3rd was not in the defendant's handwriting. He did not know whose handwriting it was in. The five letters produced, which had passed between the defendant and Mr. Cattermole, were in the defendant's handwriting.

Mr. Treherne said Mr. Graves had entrapped the defendant into an illegal act, and urged that he ought to have photographed the pictures, and put a stop to the practice of which he complained. He then urged that the convictions could not be made on each summons, but on the whole as one sale. There was only one offence.

Sir R. W. Carden said it was quite clear that Mr. Graves did not instigate the defendant to sell these photographs, he being a dealer in photographs. It is only through the machinery Mr. Graves employed that it was possible to establish a case. He was very sorry that in one week, in the City of London, he had been called upon to adjudge upon two cases of monstrous fraud. Here was a little book issued by the Photographic Protection Society, and the only parties he saw named in it were H. Ashford, the present defendant, and S. B. Beal, who was the defendant a few days ago. It appeared to him that Mr. Ashford and Mr. Beal had established this society for the purpose of promoting the interest of photographic traders, and defending it from attacks upon the alleged ground of piracy.

Mr. Treherne said that the date of that publication was February, 1865. The society was in existence then, but it was not now.

Sir R. W. Carden said that Mr. Ashford and Mr. Beal were put forward as the managers of the institution, which he had no doubt whatever was established for the protection of themselves, and themselves only. They stated that they had large funds, and he hoped there was enough to pay any penalties that might be imposed.

Mr. Treherne said unfortunately there were not.

Sir R. W. Carden was glad to hear that people had not been trapped, as he might call it, into subscribing to this society. He was sorry that two tradesmen in the City of London could act so dishonestly. As to there being but one offence, if a man could sell five hundred or five thousand photographs in one lump, and only pay a penalty of £10, there would be no protection at all, and therefore the penalty would be not only for every offence, but for every copy issued, and he was sure that this was what the Legislature intended. There had been fifty cases proved before him, and he should inflict a penalty of £5 for each case, or, in default, one week's imprisonment; that was to say, £250, or fifty weeks' imprisonment.

Mr. Treherne applied for a case to be stated for a superior Court.

Sir R. W. Carden said the application must be made in writing, and, in the meantime, the defendant could pay the fines under protest. The fines were accordingly paid under protest.

Mr. BEVERLEY announced that he should shortly read a paper on the "Dry Plate Process."

A vote of thanks was passed to Messrs. J. and J. Holderness, of Preston, for five cartes for the album, which were much admired.

There being no other business, the meeting then terminated.

## Correspondence.

### "PHOTOGRAPHY AND DISEASE."

MY DEAR SIR,—I was much interested by your article in the NEWS of last week on "Photography and Disease," having been a severe sufferer myself; and shall have much pleasure in aiding, to any extent in my power, the discovery of the cause of the deterioration of health amongst photographers.

It will be well, however, to endeavour to prove, in the first place, that the practice of photography as a profession is destructive of health; and here I am anxious to make myself rightly understood. I do not mean to assert that photography cannot be entered or carried on as a profession without suffering in bodily health; on the contrary, I believe that if the matter is well understood, and care be taken, any injurious effects may be avoided; and, having suffered, my own case is a proof that it is possible to recover. Hence the importance of some attention being given to the subject. I believe, too, it will be found on inquiry that a considerable number have suffered in a very similar manner to myself and the cases mentioned last week. I know personally of three or four such cases, and will endeavour to obtain a statement of the symptoms and any interesting particulars. If all whose attention may be called to the subject from this correspondence will record their experience, it may lead to some practical result. The medical gentleman who attended me in my illness (and who is very eminent in his profession) is much interested in such cases, and will be glad to obtain any reliable information on the subject.

My own opinion is, that the ill effects cannot be attributed to any one chemical agency, but that they are the result of breathing for several hours every day an atmosphere contaminated with noxious fumes arising from the collodion, developer, and, in some cases cyanide, to which may probably be added, absorption of poisonous substances through the skin, when the system has been already debilitated from over work, both of mind and body. You remark, very truly, in your note to "A Sufferer's" statement, that "the symptoms described are too common outside of photography." "Any occupation which overtaxes the nervous system, induces sedentary habits, and especially which occasions irregularity in taking food, may induce, in a delicate constitution, all the symptoms mentioned, quite apart from photography." But I feel convinced that these symptoms are very much aggravated in the case of photographers. True, in all the cases with which I am acquainted the system has certainly been overtaxed. There is a very great temptation to this in the case of any one who is very fond of the pursuit, and has also to make his living by it. He is never satisfied with the result he obtains; each improvement only makes him more anxious for higher attainments; hence many hours are spent in thought and experiment; and then, when rest is required, there is the work which must be done. The result is, that exercise in fresh air is neglected, and work continued to unreasonable hours. Meanwhile, the excitement and pleasure afforded by the pursuit blind him to any symptoms of injury to the constitution until it is almost too late for recovery; too late, at least, for care and exercise alone to effect a cure. Indigestion, wind spasms, violent colic pains, extreme nervousness, and something like local paralysis are induced, until the sufferer is brought to such a state of weakness as to be unable to digest any solid food. So violent at times is the pain, that the sufferer is convulsed, and symptoms not unlike poisoning by strychnine produced. The face assumes a leaden hue, the limbs become rigid, with the hands tightly clenched, and the back arched, so that the body rests on the back of the head and heels. But is it possible that this can in any way result from the practice of photography? I can only answer that such has been my experience since I became a photographer; and although not of a very robust constitution previously, I had never suffered in like manner. Whilst I continued at work I could obtain no permanent relief; but

## Proceedings of Societies.

### OLDHAM PHOTOGRAPHIC SOCIETY.

THE ordinary meeting of the above Society was held on Thursday, February 27th, the President, Mr. JOHN GREEN, in the chair.

After the minutes of the last meeting had been passed,

Mr. J. R. HENTON said that he was not quite prepared to read his paper "On Outdoor Photography" that night, but hoped to be ready against the next meeting. He would therefore read an extract from the PHOTOGRAPHIC NEWS, on a visit to M. Salomon's studio; it might prove interesting to those who had not read it.

after a few weeks' residence in the country and entire cessation from work the symptoms entirely left me, and I gradually recovered strength. With one exception, I have had no return, as I now content myself with leaving the manipulations to an assistant. The exception to which I refer occurred last spring, when I was left without assistance at a few days' notice. A fortnight's work in the dark room was again sufficient to bring on most of the symptoms I have described, although not so violent. A fortnight's rest in the country again recovered me; and since that time I have continued to enjoy sound health.

I venture to think, therefore, that my case is somewhat conclusive in pointing to the inhalation of the noxious fumes as a very great aggravation, if not the cause, of the suffering. I ought, perhaps, to say that my manipulating room is by no means small, and is provided with considerable ventilation.—I am, dear sir, yours very truly,  
J. M. BURGESS.

#### "PHOTOGRAPHY AND DISEASE."

DEAR SIR,—The two letters printed in your article of Friday last under the above heading seem to me to require notice, as apparently having an interest for all engaged in the practice of our art. At the same time, your own remarks thereon are at once so true, so judicious, and I had almost said so exhaustive, as to leave little to be desired, save that corroboration or otherwise to be obtained from the opinions or experience of other practical authorities.

As a photographer of very long experience, and also as having been originally educated for the medical profession, I may, perhaps, venture to give my opinions for what they may seem worth. Of experience in any cases of injury to health in any way attributable to the use of our ordinary chemicals I am happy to say I have had none, either in my own person or in those of my somewhat extensive list of friends and acquaintances, professional and amateur, largely or in a smaller way practising photography.

I will commence with the second of the letters in your article, as containing the more definite statement. In this, the writer (referring to chloride of silver as the supposed cause of his ailments) seems to forget that but little of that salt is present in the "washing waters," they containing chiefly—and, in the case of soft (rain) water being used, entirely—the nitrate in solution; and if any effect be produced on the system, it must surely be by the soluble, not by the insoluble, compound. It is a rule admitting of scarcely an exception, in therapeutics, that the activity of a body introduced into the system depends on its solubility, either in water (e.g., iodide of potassium) or in the juices of the alimentary canal, as carbonate of lime, though *per se* insoluble, is dissolved by acid in the stomach; or, in a third case (an example of which may be found in mercurial inunction), where the metal, in a finely divided state, is, by application to the thinnest portion of the skin in combination with fatty matter, made to effect an entrance into the animal economy. So also many solutions are now used by hypodermic injection (*i.e.*, are forced into the cellular membrane underlying the cuticle), and so become absorbed, it not being found by any means sufficient, even in the case of soluble salts (e.g., acetate of morphia), to apply them to the unbroken skin. This would seem to dispose of the supposition of the effects complained of being due even to the nitrate, the soluble salt, of silver. And I would further remark, as to the frequent use in surgery of the solid nitrate as a caustic to extensive sloughs and raw surfaces of every kind, no instance of deleterious effect is on record from such procedure. Of course the question must be looked at in two aspects: Does the silver in any form find an entrance into the system? and, if so, Does it produce evil consequences? The first question I should be inclined to answer in the negative; and, for still stronger reasons, to be stated presently, I say "No," to the second also.

Nitrate of silver, and the oxide also, are favourite (and in many cases I have known them to be effectual) remedies for certain forms of obstinate dyspepsia, they being administered in the form of pills, in doses of a grain or more, once or twice daily; the only evil, so far as I am aware, attending their employment being the liability to discolouration of the skin, which is often permanent, arising obviously from the silver entering the fluids of the body, and being so conveyed to the surface. Sir Thomas Watson, in his admirable "Lectures on

the Principles and Practice of Physic," mentions these remedies; and, if my recollection serves me, he says that of several cases of discolouration which have come under his notice, more have followed the use of the oxide than of the nitrate, clearly showing that the nearly insoluble oxide must have been taken up by the fluids of the stomach; and yet no mention is made of any further deleterious effect being produced.

Dr. Alderson, the accomplished President of the Royal College of Physicians, in his Lumleian Lectures, delivered at that College in 1852, "On the Effects of Lead on the System," mentions various methods in which that highly poisonous metal may be introduced into the blood; and in every method detailed by him—such as the contamination of drinking water, the diffusion of minute particles in oily matter, or as finely divided dust, carried into the lungs—the principle I have mentioned is evidently borne in mind. I think, therefore, that it is a fair inference, from the first of these authorities, that silver has no such effect as supposed by your second correspondent; and, from the latter, that it must be soluble salt, if any, which is the "*fons et origo mali*."

With regard to the less definite accusation against any particular chemical, as contained in the first of the letters, I am disposed to agree with you, that such symptoms are "too common outside photography." It may well be that your correspondent is not too careful, if working large plates, to avoid inhaling the highly-stimulating vapours of ether and spirit necessarily given off during coating; and in that case it is not unreasonable to suppose (indeed, I have myself experienced it occasionally) that a degree of reaction may follow the stimulating effect, and these two states, if continued, may produce, by their alternate action, forms of dyspepsia and hepatic derangement similar to those produced by indulgence to a great extent in spirituous liquors.

You have touched on one too probable cause of derangement, viz., irregularity in taking food. I know this is often a source of trouble to the class "operator," and well do I remember at one time being grudging even a quarter of an hour for luncheon and rest during the most fagging work, and at a time when, with one assistant, I was taking for the generous employer forty portraits or more in a day. Such men little know how they are in every way defeating their own dearest object, money-making; for I hold, even on physiological grounds, that the man who has an interval of rest and needful refreshment as a break towards the middle of the day, returns with renewed vigour and zest to his work; and if he be fortunate enough to have engaged with a man who values his services, and who will not cast him adrift as soon as the busy season wanes, his continuance in health is a matter of interest to his employer as well as to himself. Still, to the disgrace of many gentlemen, this and other matters of kindness and consideration to those with whose services they cannot dispense, and for whose work they take credit as their own, is a point utterly ignored.

Before concluding, one word as to a far more likely chemical to be in fault, viz., the chloride of gold, an agent more active in the system than even bichloride of mercury—abundantly soluble, readily absorbed. It was at one time (*Lancet*, November, 1852) mentioned as a remedy in scrofula; but, from the care mentioned as necessary to be observed in its administration in small fractions of a grain, it is evidently thought by those most conversant with its effects to be a dangerous remedy. How, then, may it not be liable to affect some of us? Most of us are more prone to dip our fingers into the "toning bath" than into any other solution, and doubtless this is not unattended with risk.

I remember, when having met with great success in using Hardwich's citrate of soda toning, some ten years since, I introduced the plan in an establishment, one of the printers cautioned another as to its use, saying that one of his acquaintances had been laid by with sores on the hands and arms through its employment. I did not see the case myself, nor have I ever met with a similar one since; but it shows the need of care. No doubt, from long habit, one gets indifferent, and runs risks; but by the use of proper precautions the actual contact of most of our chemicals with the skin may be obviated, or reduced to a minimum.

Apologising for the length of this note, and hoping it may reassure your correspondents in some measure, I am, dear sir, faithfully yours,  
GEO. ROBT. FIRT.

HEALTH *VERSUS* CHEMICALS.

DEAR SIR,—In the PHOTOGRAPHIC NEWS of last week I find two photographers ask as to their causes of suffering, and are inclined to attribute their illness to one or other of the chemicals they use.

Next to cyanide I believe there are no worse chemicals in general use than methylated ether and alcohol, with the free iodine usually found in many of the collodions now manufactured. These are quite sufficient to cause anyone who has many plates to sensitize to feel very unwell, unfit for work, and inclined to be careless about other manipulations. Some guide-books actually advise that dirty plates should be cleaned with old collodion with an addition of iodine. This, I know from practice, is most injurious to the eyesight, as well as hurtful to the health of those who inhale methyl and iodine. I usually coat my plates in a glass studio, and then take them into the dark room to place in the nitrate bath, covering the bath over with a brown paper cap, and not shutting the door of the room until the plate is ready to take out of the bath. Even with this large space to work in, I am constantly told, when away from work, that I smell horribly of collodion: to such an extent does the vapour impregnate everything that comes in contact with it, and, of course, the breath also.

When, formerly, in the habit of buying my collodion ready made, I almost thought I must give the fine art up, in consequence of the effect the effluvia had on me; since then I have generally made my own collodion, and advise all others to do the same. My manufacture is not quite so sensitive as some I can purchase, but I find it does not injure my health when pure spirit is used. It answers much more surely for dry plates, and my nitrate bath now keeps in good working order double the time it formerly lasted. It is also cheaper to make collodion from pure spirit than to buy methyl collodion.

The receipt is most simple. The only difficulty is in procuring good pyroxyline, if you do not make that also. In making collodion, never use from one sample of pyroxyline only, but take from a mixture of at least half a dozen different lots, so as to make an average.

*Plain Collodion.*

11 ozs. pure ether at 4s. ...	2s. 2d.
10 ozs. pure absolute alcohol at 5s. ...	2s. 6d.
150 grs. pyroxyline at 2s. 6d. ...	0s. 10d.
	5s. 6d.

*Iodizer.*

7 ozs. pure alcohol, S12 at 4s. 6d. ..	1s. 7d.
84 grs. iodide cadmium } 161 grns. ...	
42 grs. bromide cadmium } at 1s. 9d. ...	0s. 8d.
35 grs. iodide ammonium } (say) ...	
	2s. 3d.

Total cost of 28 ozs. collodion ...	7s. 9d.
Or 5s. 6d. per pint of 20 ozs.	

Add a few drops of tincture of iodine to the collodion before using—just to make it a straw colour—and it will keep good for many months. M. W. J. S.

*Lavender Hill, Wandsworth, March 2nd, 1868.*

PS.—The plain collodion to be drawn off with a syphon, so as to be clear of sediment; and the iodizer to be filtered through paper.

## COMMON WATER FOR NITRATE BATH.—PERMANGANATE OF POTASH.

SIR,—As there has been some correspondence lately on the use of common water for photographic purposes, perhaps a few remarks may not be amiss from one who, like Mr. N. K. Cherrill, has proved that distilled water is not at all necessary for any of the baths or other solutions used. From the commencement of the collodion process I have never used any other but common water for developing solutions, &c., and for some years have used only common water for the negative bath. By the same plan that Mr. Cherrill recommends—viz., by adding about half a drachm of an old negative bath to about forty ounces of common water from any pump or river, then filtering, and adding the proper quantity of silver, as usual for a bath—it works well and makes clear negatives. If it should not do so on trying the first plate, a single drop of nitric acid has put all right.

In June last I was at Fountain's Abbey taking views, and, by accident, a lady's dress caught the corner of my tent and upset it, and wasted all my silver bath; and as I was four miles from Ripon (the nearest place that distilled water could be got), it was not pleasant to walk that distance and back with a bottle of distilled water; but as the bath that had been wasted had been made of common water before I left home, I saw no reason why I should not make up a bath with the water that was running close by, as I had several ounces of nitrate of silver in my box. I took a large can and went to the river and filled it, but as there had been rain the day before, the water was a little sandy and muddy. I measured out 60 ounces and placed a few crystals of silver in it; after shaking well, filtered it, and then dissolved the proper quantity of silver to make a 30-grain bath. I then tried a plate. The negative looked a little misty. No. 1 print enclosed is from the negative. I then added one drop of strong nitric acid, took another plate, which made all right. Nos. 2 and 3 prints were taken after this drop of acid had been put in the bath. I will leave you to judge whether they are or are not as clear as though they had been from negatives done in a bath made with distilled water. I may say that I took more than a hundred negatives after these, in the same bath, and all worked as well.

It may be said that in another part of the country the nearest river water would not work so well. All I can say is, I have never met with a failure in that direction, and I have worked in almost all parts of England, taking views. I also have used the water that runs in the rivers through the valleys in Switzerland with the same good results; but, in nine times out of ten, simply taking the proper quantity of water and adding the silver will make a first-rate bath, even without filtering; but should there be any signs of milkiness, then filtering will be necessary.

I have been trying the permanganate of potash cure for an old, foggy bath, and find it to answer for that purpose better than anything I have ever tried before. I enclose you some prints to show the difference before and after the addition of the permanganate. This bath, that the negatives of these prints were taken from, was one to which cyanide of potassium had been added, but would not cure it. Carbonate of soda had been put in it and sunned for two days in very bright sun, then it would not work without fogging the negative. I then got a little permanganate of potash and made a solution of 20 grains to the ounce, and added as much as made the bath the colour of dark sherry, which remained that colour for about ten minutes; it then gradually began to turn brown, and went on in that direction for about two hours. I let it stand about another hour, and a rusty-looking deposit began to go to the bottom of the bottle. I then run it through a clean filter, and it filtered as clear as possible. I then tried a plate, and it made a negative in every respect as clear and as good as any new bath would in the best of conditions, and with only one application of the iron developer, which, it will be as well to say, was made with sulphate of iron 20 grains, sulphate of copper five grains, glacial acetic acid one ounce, spirits of wine half an ounce; the time of exposure was about the same as with a good new bath. Perhaps, Mr. Editor, you will examine the prints done before and after the addition of the permanganate of potash, and state how far you think it has accomplished the object.—I am, sir, yours truly,

GEORGE WILLIS.

*32, St. Nicholas Cliff, Scarbro', March 2nd, 1868.*

[The examples enclosed fully illustrate our correspondent's statements.—ED.]

## Talk in the Studio.

PORTRAITS A LA SALOMON.—We have just received some exceedingly fine examples of portraiture from Mr. Notman, of Montreal, treated after the manner of M. Adam-Salomon, and in many points resembling them. We shall have more to say respecting them shortly.

ENAMEL PHOTOGRAPHS.—We recently had an opportunity of examining some of Mr. Jonbert's photographic enamel miniatures produced by a modification of his patented process. The results are admirable, soft, round, and delicate, yet lacking nothing of vigour, and many of them excellent in colour. Mr. Henderson recently exhibited some very promising specimens by a process he has recently worked out, the details of which

he does not make public. We believe that there is a more extended popularity in the future for this kind of photograph than it has hitherto obtained.

**CURIOUS CAUSE OF WEAK PRINTS.**—A correspondent calls our attention to a singular cause of flatness and weakness in prints. An example recently sent to us had the appearance of having been produced from a weak fogged negative, but was, we were assured, obtained from a very vigorous negative. He now explains the cause as follows:—"You will perhaps remember that some weeks ago I sent you a print, on roller, of group of lady and boy, asking you if you could tell me the reason of the want of force it showed. Not having seen the negative, you attributed the fault to that being fogged, or some other fault that you thought belonged to the negative. I have since obtained brilliant prints from the same negative, and have discovered the cause of the badness of several prints that were made at first, and were like the one I sent you. My brother, who had made the prints, to prevent the paper cockling, had dried the cloths, &c., which formed the packing, and had put them on the paper while still warm, and thus spoilt the print."

**SUGAR IN THE PRINTING BATH.**—A correspondent, J. S. W., sends us an example of the value of sugar in the printing bath, with the following note:—"Having derived much valuable information from your pages, and as you request points of practice, I enclose you a bit of paper sensitized three weeks ago, and a print taken on some of the same paper, and as dark before toning. The bath had sugar in it, as recommended by Mr. Bevey, to whom many thanks are due, but who would hardly recommend so severe a trial as to its result. You will judge for yourself." The enclosure is an interesting picture, and a good print.

## To Correspondents.

**C. E. F.**—Condy's fluid is a solution of permanganate of potash, containing, we believe, about 20 grains per ounce of the salt. It may be used for removing organic matter from either printing or negative bath. A more dilute solution will, however, be safer to use. See an article on the subject in our present number. The same instructions are applicable to the printing bath. Permanganate of potash may be obtained of most chemists. 2. The enamel paste with a basis of wax like that referred to may be obtained ready for use of various dealers in photographic materials. Newman's enamel paste answers well. You may prepare such a material yourself by dissolving pure white wax or paraffine in an essential oil, like that of lavender, in proportion to make a stiff paste.

**ACID GOLD.**—The object of neutralizing chloride of gold for toning purposes is to secure a condition in which the gold will be readily thrown down on the print. When excess of hydrochloric acid is present, it is often difficult to secure satisfactory toning action. If you secure good toning results with an acid bath there is no reason why you should not use it; but it is important in such case to rinse the prints very thoroughly before immersing them in the fixing bath, as otherwise the acid in the print would decompose the hypo, and cause sulphur toning.

**W. J. A. G.**—The waterproof fabric you enclose will answer well for covering a tent; but it will be desirable to have an arrangement in a tent so covered for ventilating purposes. 2. The price of the *Philadelphia Photographer* is 50 cents (2s.) each monthly number. 3. We have seen so called "instantaneous" pictures produced on dry plates; but they were not what we should term good. The term is, of course, purely relative; we hear many things in photography called good which are, in our estimation, very inferior indeed. We have taken instantaneous sea views on Dr. Hill Norris' extra rapid dry plates, which were pronounced "good for dry plates," but which were poor when judged by a standard of excellence attainable on wet plates.

**C. M. (Rennes).**—We have carefully tested the mounting cards of the stereo prints, and do not detect the presence of hypo or other sulphur compound. After a careful examination, we can only come to the conclusion that, owing to some oversight in the manipulation, or some impurity in the hypo, the prints were imperfectly fixed, and contained, after finishing, insoluble hyposulphite of silver, which decomposed under the action of moisture and light whilst mounting. 2. The cracking of the negatives of which you send example seems most probably due to damp acting upon some trace of a hygroscopic salt left in the film, either by imperfect washing, or from washing in water containing traces of some such salt. Rubbing with very finely powdered charcoal on a tuft of cotton-wool will fill up the cracks considerably, and

sometimes permit of the production of a tolerable print from such a negative.

**COMO.**—For direct sun printing with the solar camera, without development, a similar process may be used as for ordinary printing in the pressure-frame. If the paper be prepared expressly for the purpose, a strong solution will increase sensitiveness; about 15 grains of chloride of ammonium to each ounce of albumen may be used, and a silver bath of 80 grains to the ounce. For development printing with the solar camera, 8 grains of bromide of potassium, 4 grains of chloride of ammonium, and 3 grains of gelatine in an ounce of water form a good salting solution. This paper may be excited on a 60-grain silver bath containing about 5 drops of acetic acid.

**D. M. A. (Montrose).**—There are several modes of taking several images on one plate; whether yours is new or not we cannot, of course, tell you without knowing the details. The expense of protecting the method, if new, would be somewhat heavy, as it could only be secured by patent, which would cost upwards of £50 for the first three years, and between £200 and £300 for the whole term a patent can run; namely, fourteen years.

**WALTON ADAMS.**—Mr. Werge, at Mr. Hughes', 379, Oxford Street, is a clever Daguerreotypist, and he will probably undertake a commission to clean and recolour a Daguerreotype for you.

**OBEDIENT SERVANT.**—Thoroughly damping the engraving all over before mounting it, and also damping the mounting-board, will doubtless remove the cockling which exists. After mounting, let the mounted picture dry under firm pressure.

**G. STEWART.**—The excited samples of paper, after exposure, give such stains as you describe; the pieces which we excited did not, but there were a few spots of discolouration. Nevertheless, we are inclined to believe that the fault is in the paper. We notice that, on removing it from the silver bath, it possesses an offensive smell of sour and decomposing albumen. It is probable that the paper has been kept in a damp place, and some decomposition in the albumen set up.

**W. G.**—The singular and polychromed bronzing which remains after toning and fixing is unusual, and we cannot certainly indicate the cause. The use of a weakly salted paper and a strong silver bath with negatives possessing much contrast is a common cause of bronzing. Try the use of a weaker silver bath.

**A PROVINCIAL PHOTOGRAPHER.**—For enlarging by means of artificial light an ordinary magic-lantern condenser will answer well. A combination formed of a double convex and concavo-convex in contact will serve your purpose. If you apply for a magic-lantern condenser, instead of for a condenser for enlarging, you will receive the right thing.

**NOVICE.**—Undoubtedly a coloured transparency of a painted glass window will do it more justice than an ordinary paper print. 2. A very roughly coloured print, taken on the spot, will serve as a guide for the colourist. 3. Your doublet will answer well for the purpose; but we cannot possibly give you any idea of the exposure necessary, as so much depends on the light, the colours in the window, &c. You can only ascertain certainly by experiment.

**A. McD.**—We fear that the matter is a swindle, and, if we are rightly informed, the instrument is quite worthless when supplied. You can obtain the *YEAU-BOOK* by post on sending 1s. 2d. to our Publisher.

**NOVICE II.**—Alcohol performs no office in the developer beyond making it flow freely over the plate. Methylated spirit will answer perfectly.

**REV. A. S. (Devizes).**—The description in question is published in two numbers of the *PHOTOGRAPHIC NEWS*, October 18th, and November 8th. In our experience, and that of the majority of our friends, the process answers perfectly if the plates are used within a week after their preparation. The best commercial dry plates we know are those of the Liverpool Dry Plate Company. We have never met with a failure even after long keeping.

**BEGINNER.**—It is probable that increasing your north light and removing the south light will give you improved results, as you suppose; but the lack of definition in the enclosed print is not, we think, due to imperfect illumination. It is probably due to the use of a lens with short focus with too large an aperture. Try inserting a smaller stop, and send us another example.

**COLLODION.**—It appears probable that you had over-iodized your bath; and diluting with distilled water, filtering, and then strengthening will prove a remedy. 2. Better try the morphine alone. In the majority of hands, it has answered well. That, or Mr. England's process, will probably best serve your purpose. 3. *Rive* paper gives the most brilliancy, and is most suitable for soft negatives; *Saxe* paper gives the most softness, and is suitable for hard negatives. For good negatives, we prefer *Saxe*.

**BONA FIDE** and several other Correspondents in our next.

### THE LONDON PHOTOGRAPHIC SOCIETY.

The conviction we recently expressed as to the vitality of this Society received satisfactory confirmation at the meeting held on Tuesday evening last. An excellent paper by Dr. Mann, on "An Amateur's Difficulties in South Africa," and the discussion thereon, engaged the greater part of the evening, leaving no time for a further communication from Mr. J. R. Johnson on the use of permanganate in rectifying disordered nitrate baths. Amongst other interesting objects shown, we may especially note some exceedingly fine portraits after the style of M. Adam-Salomon, exhibited by Mr. Fradelle and by Mr. S. Fry, the pictures of both gentlemen possessing many of the characteristic qualities of force and chiaroscuro belonging to those of the great French artist.

But good papers, interesting discussions, and fine examples of photography have not been rare at the Society for some time past; and it is to a gratifying announcement made by the Chairman we especially refer, as illustrating the vital interest taken in the Society by its leading members.

Mr. Reade announced that, to aid in giving a new impulse to the Society, Mr. H. P. Robinson had volunteered to produce during the year an especial subject-picture for the Society, and present each member with a print. Mr. Henry Claudet had undertaken to present each member with a print from the last negative taken of his father, the late Mr. Claudet, the portrait having the additional interest of having been produced by the topaz lens which Mr. Claudet had recently had made. Mr. H. Claudet here happily illustrates his own cordial feelings towards the Society, and confirms the statement we recently made, by his desire, as to the absence of any feeling of antagonism between his late father and the Society. Mr. England had also undertaken to produce, during his summer tour, an especial negative, for the purpose of presenting prints from it to the members. It is probable that the pictures of the two first-named gentlemen will be ready for presentation some time this year; that of Mr. England may possibly be delayed until the beginning of next year, as the opportunity for producing such a picture as Mr. England may desire for the Society can only be taken in such part of the season's tour as may be suitable. We congratulate the members on the promise of three such pictures, and we echo the statement of the Rev. J. B. Reade from the chair, that such offers from such gentlemen prove, "in spite of the breezy little notices got up from time to time intimating that the Society was going down, that its motto was still *Excelsior*."

### KEEPING THE NITRATE BATH IN ORDER.

We are indebted to Mr. Rejlander for a practical suggestion for the preservation of the nitrate bath, which seems as philosophical as it is, he informs us, efficient in practice.

Reflecting recently on the causes of fog, stains, and other troubles arising from the condition of the bath, he arrived at the natural conclusion that they were due to the presence of bodies with an abnormal tendency to reduction. The nitrate bath, he argued, should not contain anything which is in itself sensitive to light, or anything which is readily reduced by the action of a developer, except in those parts forming the image. The plate, when it leaves the bath, should contain nothing which will be readily reduced without the action of light, and where light has not acted reduction should not readily take place. That, of course, is a proposition familiar to every photographer who attaches due value to clean shadows. These conclusions arrived at, Mr. Rejlander resolved to employ light as the touchstone of the condition of the bath and the remedial agent at the same time, commencing to remove the evil as soon as it indicated its presence. As the nitrate bath should not in itself be sensitive to light, nor contain substances so sensitive, he resolved to use light as a detector of the presence of any intruder in the bath; and instead of sunning his bath occasionally to get rid of such intruder, he resolved to do it constantly, to detect the first approach, and eliminate the first appreciable accumulation, of organic matter. In short, opposed to all old rule, he keeps his nitrate bath constantly in daylight when not employed in sensitizing plates. Whenever any foreign substance which combines with silver or tends to reduce its salts is present, the action of light will reveal its presence by the discolouration and turbidity which will ensue, and it will, at the same time, commence its elimination by reducing it, so that it may be removed by filtration. Mr. Rejlander states that he has now been trying the plan for some little time with complete satisfaction. When he finds a bath discoloured by the action of light, he knows, of course, that it is not fit for use; but by constantly keeping his baths in the light, the work of elimination going constantly on, filtration generally removes the matter thrown down by light, and he always has a bath in perfect condition, yielding him brilliant and clean negatives.

There is the possible objection to this method that light will aid in setting up injurious decomposition in the organic matter accumulated in the bath, which might otherwise for some time have remained inert, producing no injurious effect by its presence. This argument will, however, be chiefly of weight against the use of the bath in an intermediate condition, when light has acted sufficiently to initiate decomposition without completing the reduction. Other objects may arise in the course of extended experience; but, in the meantime, the suggestion seems valuable, and is worth a trial. In the early days of the collodion process the strictest care was enforced as to the preservation of the nitrate bath from even a passing gleam of light. Since then sunning has become a recognized remedy of the utmost value for an old disordered bath; and it is possible that the continued action

of light may aid in the constant elimination of the gradual accumulation of such bodies as produce fog or other abnormal reductions.

### SIMPLE METHOD OF WAXING PRINTS.

MR. BLANCHARD has called our attention to a simple method of waxing prints, which he has been practising some time with great success, and which he finds quite as effective, with much less trouble, than the ordinary method of employing enamel or encaustic pastes in the usual way.

Instead of employing white wax, which is frequently adulterated with fatty bodies and so rendered comparatively worthless or absolutely injurious for finishing photographs, he takes common bees'-wax and dissolves it in benzole, making a solution of about the thickness of cream. From two to three drachms of bees'-wax dissolved in an ounce of benzole we find, by experiment, gives about the right result. This is smeared all over the face of the print, the benzole evaporating almost as quickly as the preparation is applied. It is then polished by means of brisk friction with a clean cloth; we find that a silken fabric answers best. The result is a rich depth in the shadow, more detail in the lights, and a waterproof surface which will materially protect the picture from various injurious influences. After this treatment the surface is hard and firm, and does not readily mark with handling; and if it eventually becomes dull, dusty, or a little marked, brisk rubbing with a piece of clean cloth restores the polish. Mr. Blanchard finds that this mode of finishing the prints is quite available commercially: a couple of girls engaged on the work, one applying the wax and the other giving the polish, rapidly get through a large number of pictures. The tint of ordinary bees'-wax does not communicate any perceptible colour to the prints.

### RESTORING AN OLD BATH WITH PERMANGANATE.

WE have within the last few days applied the permanganate remedy to an old bath sent up to us a few weeks ago by a correspondent for examination. It consisted, according to the description, of a mixture of an old bath which had been evaporated to dryness, and redissolved in distilled water, with an equal bulk of a new silver solution. Such a mixture might have been expected to work well, but it did not. It was described as giving streaks and other markings which could not be got rid of. In our hands, although the streaks were absent, it yielded a thin, poor negative, with a grey, foggy deposit, not loosely on, but in, the film. The result was the same with two or three samples of collodion.

In this instance we employed Condyl's fluid, which is accessible to all our readers, being sold by most dispensing chemists, who rarely keep the salt in crystals. To six ounces of the nitrate solution about twelve drops of Condyl's fluid were added, the solution being briskly agitated. The purple tint at first produced gradually changed—in about five minutes—into a grey, and in about a quarter of an hour all purple or pink tint had disappeared, a light-brown coloured turbidity only remaining, which was filtered out, and a plate was tried in the solution. A vigorous image, but slightly veiled, was the result. As the solution was quite neutral when tested with litmus paper, a drop of nitric acid was added, and another plate tried. The result now obtained was a perfectly clean and vigorous negative, dense, and with a fine bloom in the lights, and absolutely clean and transparent in the shadows.

To a small portion of the original solution we added the permanganate solution in a much larger proportion. This was several hours before it lost the pink tint; the precipitate, which was of darker brown than before, was found, on examination, to contain permanganate of silver mixed with the sesqui-oxide of manganese; thus illustrating that the addition of excess of the permanganate only issues in waste of silver.

## Foreign Miscellanea.

**PHOTOGRAPHING COAST SCENERY FROM THE SEA.**—M. Julius Kruger, of Stralsund, publishes in the *Photographische Correspondenz* a very interesting paper on photographing coast scenes from the sea. He has secured some very charming views of Sassnitz, a small watering-place in the island of Rugen, and he has been led, by the success of his enterprise, to publish the details of the method by which the pictures were produced. The principal conditions required for the production of a good photograph are perfect stillness and rigidity of the camera, and the reflection upon the ground glass of a sharply defined image. To ensure these conditions it was impossible to work from a boat or raft, as even during the finest weather the same would be subject to slight oscillation; M. Kruger, therefore, constructed a large tripod-stand composed of three masts, each measuring thirty feet (the depth of the sea at the point selected for operating), and these, having been firmly braced together and loaded with a few heavy chains and weights, were lowered at the desired point, which had previously been marked by a small buoy. The camera was fixed to the top of this stand, and a small row-boat, provided with a dark tent and the necessary appliances, contained the operator. At first, great difficulty was experienced in exposing the plate, as the boat was continually drifting away from the camera; and it was impossible for the operator to hold on to the stand, or to keep the boat in position by rowing, as either mode of proceeding had the effect of shaking the camera. By mooring an anchor at the prow and stem of the boat this difficulty was overcome, and, by the employment of a very small diaphragm, the picture did not suffer any injury from an exposure of two or three seconds more or less. M. Kruger believes that it would be quite possible to work in water of much greater depth, although it may be assumed that in most cases the sea is never much deeper than thirty or forty feet in such close vicinity to the shore.

**PHOTOGRAPHIC ENTERPRISE IN AUSTRIA.**—In the same journal is published a computation of the number of carte-de-visite photographs which have been produced in Austria during the past year, and which shows that photographic trade is by no means at a stand-still in that country. Half a million dozen of pictures is the supposed number, which, calculated at three florins per dozen, would give a total of a million and a half of florins received by Austrian photographers.

**SECURING FIRM FILMS.**—At a recent meeting of the Berlin Photographic Society some discussion took place as to the best method of producing a firm, adherent collodion film. Dr. Vogel gave it as his opinion that the quicker the solvent evaporated the firmer would be the film, and it is for this reason that better films are obtained in summer than in winter. He suggested that collodion manufactured for winter use should contain an additional quantity of ether. M. Grune believed that a rotten film was the result of employing collodion prepared with imperfectly-washed gun-cotton which had been treated with alkali.

**PHOTOTYPES.**—The *Photographische Mittheilungen* contains a capital engraving, said to have been produced from a plate from which 30,000 copies had previously been struck off. It is a so-called phototype, and is a reproduction of a pen-and-ink sketch; it was produced by the process of MM. Burchardt Frères.

**PHOTOGRAPHIC RELIEF FUND.**—Both the Berlin and Hamburg Photographic Societies have been endeavouring to establish a fund for the benefit of photographers' widows, but, unfortunately, up to the present time without success. Meanwhile, the formation of a mutual assurance society is contemplated.

### PHOTOGRAPHIC PRINTING IN SILVER, THEORETICAL AND PRACTICAL.

BY W. T. BOVEY.

#### REMARKS ON PHOTOGRAPHIC PAPERS, ETC.

MEASURED by its rapid growth, or the precocity that has characterized its every stage of development, photography has no parallel. Although its existence in a practical form scarce reaches thirty years, yet its history admits of distinct

divisions: First, the era that was inaugurated by the renowned Daguerre; second, the revolutionary advent of collodion as a photographic agent; and it might be recorded, as an interesting fact, that a worker of Archer's invaluable process, whose experience dates beyond some half a dozen years, numbers with the pioneers whose exquisite skill and undaunted perseverance have elevated the art of photography to a position of importance, which finds a ready recognition among all classes of society.

The rage for stereographs which for a time ran rampant did much towards popularizing the art, but it is to the carte mania that photography is indebted for the proud position it has since attained. No sooner was that style of portraiture in miniature form introduced, than the public, enamoured with the novelty, eagerly crowded the photographers' studios. A race for excellence was the result; and experimentalists joined heart and soul in searching out the conditions requisite to secure the maximum of sensitiveness, delicacy, brilliancy—in a word, perfection. In pursuit of these the indefatigable explorers laboured unceasingly; nor did they prospect in vain, as the objects sought were speedily discovered; and had the discoveries which enabled all that was needed in the production of a negative to be held in subjection been supplemented with some satisfactory contrivance by which the positive proofs would be mechanically reproduced on a paper surface, photography, apart from the demands of educated art, might have been pronounced a perfect success. But it unfortunately happens that from the birth of the collodion process a hydra-headed difficulty has presented itself, in the fact that the picture so delicately and beautifully traced in the collodion film cannot, with freedom from the elements of uncertainty, be satisfactorily impressed on paper; and as the problem of unswerving success still remains an open one, the reason of failures and the means to overcome them are the questions on which I now enter; and the first in the order in which I propose dealing with each subject that presents itself being paper, that of paper I now, without further digression, proceed to discuss; and as I am desirous of being understood by all readers, I shall here dismiss the rules that belong to strict composition, and write as if I were engaged in friendly chat.

My troubled reader, I have listened attentively to the numerous failures you describe, and which you attribute to "that abominable paper," and, by way of consolation, my endeavour will be to remove the erroneous impressions which have found a harbour within your bosom. You say you are unable to get at the tone you aim at; your pictures are weak, washy, and mealy; in every sense of the word miserable failures; and, as a slight relief from your troubles, you thrust the bulk of your difficulties on to the shoulders of the paper dealers. Stay, friend! suspend false reasoning whilst I endeavour to set you on a better and more reasonable track. You will doubtless admit that the object the dealer holds chiefly in view is to secure customers, and however dishonest in the core a dealer may be, self-interest whispers in his appreciating ears, "Get customers; and when, by advertisement allured, to retain them in these days of trying competition you must keep and supply the best possible article." And the anxiety to observe this sensible advice is made evident by the improvements which of late years have been effected in the manufacture of photographic papers by continental manufacturers, who, for once, have distanced Albion, and have left their English competitors far behind; so far, indeed, that the papers which are chiefly—I might say invariably—employed for direct photographic printing are purchased in the continental markets, and are recognized as Saxe papers when procured from Germany, and Rive as manufactured in France. Both kinds, by separate workers, are made special favourites, because their varying qualities meet the variable demands of negatives that differ in their printing qualities. Saxe papers, being of a soft, porous nature, are proved best adapted for printing from vigorous negatives that need the

softening influence exercised by the paper named; whilst for feeble negatives the Rive papers are found most suitable for obtaining the best results, because of their hardness of texture, which renders the paper more impervious, and thus retains the picture on their surface. In my own practice, for general purposes I much prefer the Saxe papers, on account of their desirable working qualities; and the article as prepared by the celebrated Steinbach, of Malmedy, is as near perfection as I believe it possible to go.

Saxe papers have, as now made, a pleasing blue tint; Rives have a creamy hue, and the reputation of this last-named paper suffers much because of its proneness to stars and comets, which have been erroneously attributed to the proximity of the mills in which the papers are produced to some kind of iron works. The great iron works, however, may be sketched in the form of a brass or iron button, which the rag-sorters have carelessly overlooked. In justice to paper-makers, I shall find occasion, in due course, to point out an unsuspected reason of metallic blotches, which, I trust, will remove some amount of the odium from the parties usually blamed. It will be unnecessary for me to deal exhaustively with the unprepared papers by describing their varying weights and thickness. I shall therefore proceed with a description of the treatment papers undergo when handed over to the tender care of the (mis-called) "photographic paper manufacturers."

As I before observed, the point held most prominently in view by the paper preparer and dealer is to secure for use the highest class of material his money can purchase; and he takes care to examine closely every sample he purchases to satisfy himself that the texture is of the finest, the surface of the smoothest description. When satisfied with the article provided, he proceeds with the preliminary operations, which advance the paper a stage in a photographic direction. In the treatment to which the papers are submitted, two distinct principles have to be considered: first, the elements of sensitiveness which are supplied by the chloride employed; second, an organic agent must be supplied to impart stability and vigour, without which the hypo solution converts a silver print into an unsightly affair indeed. Now, as the relative proportions of the agents named by modifications exercise an influence that changes the character of the silver prints, the paper preparer has to arrange his formulæ to meet the varying requirements of his patrons. Some few years ago, when "soot and whitewash" was the facetious character attached to photographs, a highly salted paper was generally used, and consequently a strong silver solution was an absolute necessity; but at the present time, negatives by improved chemicals and treatment are more perfect, which renders a strong salted paper unnecessary; indeed, papers weakly salted have therefore become the rule, and their introduction has enabled photographers to improve the beauty of their pictures to a remarkable extent.

The desirability of paper dealers informing their customers somewhat concerning the amount of salt present in the papers they supply has frequently been urged by the editors of photographic journals. But the information would be next to useless to its recipients, who can, if they please, give a near guess without assistance, if they will examine the prints as they leave the printing-frame. The larger the proportion of chloride salt present, the deeper is the violet tint observable in the print, and the greater is the reduction in the hypo bath. A weakly salted paper prints more red on account of a large portion of the picture being composed of reduced albuminate or other organic salts of silver. The paper selected for examination should be perfectly dry, and the printing should be conducted in diffused light; otherwise the test is not a reliable one, as dampness removes the violet colour, and sunshine would, by rapidly reducing the organic salt, impart a red tint to the picture.

The chloride salts which may be employed for salting papers are numerous. Making the salt of ammonium an exception, I can see but little difference in the results pro-

duced by the remainder, if the variations in equivalents are allowed for.

I just now observed that an organic substance is provided to impart vigour; but, setting aside plain salted papers, it performs a double part, its presence being necessary in keeping the picture on the surface of the paper, without which the larger portion of the delicacy observable in a good negative would be lost in the body of the paper. With reference to the question of exact reproduction, it is probable that no paper surface registers faithfully all the details seen in a perfect negative; its extreme delicacy has no echo. This is made perceptible if we compare a collodio-chloride print with its duplicate formed in albumen; but, in the absence of something better, the substance last named has been selected for the most active photographic service, and is the article well known as being the chief agent used in the preparation of photographic papers. Although an albumen may be procured from the blood of slaughtered beasts, it may be accepted, as a rule, that no paper preparer who has a sensitive nose or a reputation to preserve, will use any other kind of albumen than that procured from the freshest of eggs; and as he is compelled to advertise his wares as something special and distinct from all others, the honest dealer finds a field for his ingenuity in the varied proportions of salt admissible, which enables him to number his papers or apply fanciful names to his heart's content. And as albumen admits of admixture with water, a keen-witted paper albuminizer, who makes the running in the race of competition, may, if it so please him, advertise single, double, or treble albuminized papers with but little extra labour bestowed in their preparation. Unless the first coating of albumen is coagulated, no advantage is gained by applying a second floating; but the highest glaze is attainable by using the thickest part of the albumen. It should, however, be understood that the highest glazed papers are the most liable to blistering, which, I think, is most reasonably accounted for by attributing the cause to imperfect coagulation of the inner surface of the albumen, so that, when an influence (hereafter to be explained) is exercised by the washings that follow fixation, the albumen quits its hold of the paper, and blisters directly from.

It is quite possible to prepare a highly glazed paper without having recourse to strong albumen; in such case the pores of the paper are filled in with some neutral material—such as carbonate of lead—which is brushed on the paper, and subsequently smoothed and polished. The difficulty experienced in procuring a satisfactory paper with an enamelled surface has prevented its general use. I hope, however, that I shall shortly be in a position to pronounce the difficulty removed.

And now, in conclusion, a word to those who are sighing and longing for a self-acting paper, warranted free from failings or failures. My dear grumblers, the papers supplied to you and me, and all others, are probably by the same makers, manufactured in the same mills, and, if procured from respectable dealers, they are, photographically, prepared with the same kind of material; and the only reason why one paper is found to suit better than another is because the salting formula varies as adopted by various makers, and as you will not, or cannot, modify your mode of working to suit the paper, you have, perforce, to go the rounds of paperdom until you find an article that meets your desires. Hence A's paper just meets the wants of B, whose toning solutions are most unmerciful in its bleachings, and B is in raptures; whilst C, whose gold solution does not bleach at all, is wishing A at Jericho, and his paper with him, because of the over-vigorous lot of pictures the paper has produced; and so matters unamicably jog on. Poor paper albuminizers have more blame than praise bestowed on them, and the question arises: Why? Because our toning operations are based on false principles; because we have been straining at complications, where all should be simplicity. But, taking things as they are, why not dealers

supply papers suitable for all customers? My dear Querist, would you like to be clerk of the weather, if you were bound to comply with the wishes of all wishers? Imagine the task, and you can understand why paper albuminizers fail in their efforts to satisfy all comers. With this remark, I close the subject of paper for the present; and I may announce that my next article will be on the important subject of sensitizing solutions.

## ON THE CAUSE OF DETERIORATION OF PRINTS MOUNTED ON CARDBOARD, WITH GILT BORDERS.

BY MM. DAVANNE AND FORDOS.\*

M. FORDOS recently received from a photographer residing in a provincial town in France a series of *carte-de-visite* pictures, all of which had been rendered useless by the formation upon their surface of very minute black spots. Imperfections of a similar description had previously been noticed by M. Davanne, whose attention had been called to the fact by M. Dauvois; and at that time M. Davanne attributed their causes to imperfect fixing. On attention being called a second time to the subject, and assurance being given that the prints thus injured had been manipulated with the greatest care, it was deemed desirable to make an investigation into the matter.

Inspection alone was sufficient to banish all suspicion that the prints had been imperfectly washed, for if such had been the case, the hyposulphite of soda, being contained equally throughout the print, would have had the effect of injuring the picture in a more general manner; or had the damage been visible in certain places only it would have taken the form of large yellow spots, always increasing in size. The idea next suggested itself that the fixing of the prints had been incomplete, and that the hyposulphite of silver formed in the print when the latter first comes into contact with the hyposulphite of soda had not been completely dissolved out, but had resisted the action of subsequent washings. Imperfections similar to those under investigation may be caused in this manner, but in such a case the damage becomes at once apparent, and would be remarked as soon as the prints were mounted. Besides, with spots of the kind just alluded to, the print, when viewed as a transparency, exhibits opaque patches corresponding to themselves on the surface; while in the present case the colour was destroyed by the minute imperfections and the transparency of the print not interfered with.

The information given by the photographer who produced these injured prints was to the effect that with the same materials in the same batch of prints, some of the pictures produced become damaged, whilst others remained perfectly free from blemish; for this reason it was supposed that the cause of deterioration existed in the cardboard.

Following up this idea, it was thought that the cardboard might contain some minute proportion of hyposulphite of soda, a material frequently used in the manufacture of paper. At the same time, if such were the case, the hyposulphite ought to have attacked the print in a more uniform manner, for it would be distributed in solution throughout the entire bulk of the paper; and even admitting, as an extreme case, that it had become crystallized in minute particles upon the surface of the board, it is evident that the moisture contained in the mounting material would have at once dissolved these crystals, and prevented them from remaining isolated in certain places only. Again, the hyposulphite of soda introduced into the paper pulp might have been subjected to partial oxidation by the bleaching chlorides, and the traces of sulphur thus disseminated might afterwards have exerted a destructive action; it is just possible that this might have occurred, but in such a case a much larger number of pictures must have suffered, and at present we have to do merely with exceptional cases.

\* Read before the French Photographic Society.

A last hint might help to solve the difficulty: the imperfections occurred only in pictures surrounded by gold or bronze borders, and not upon those ornamented with borders of a different description. It was probable, therefore, that the bronze powder was the cause of these innumerable spots, and, in order better to understand this reasoning, it is sufficient to call to mind that the method of printing cards of this kind is different to that generally pursued. The design is first printed, with adhesive varnish, upon the card from a lithographic stone, and the bronze powder is then sprinkled over it; the powder adheres to the varnish, and a design is thus produced in bronze or gold. But the paper employed is not so smooth but that it can retain upon its surface minute particles of the powder, which thus remain under the mounted photograph, and may lead to the deterioration of the print, supposing the bronze material contains any noxious matter. Now it so happens that these bronze powders are mostly composed of bisulphide of tin—that is, a compound of sulphur and tin—and this material may, from the mode in which it is manufactured, contain traces of free sulphur. To be convinced of this, it is merely necessary to rub a small quantity of the powder in a mortar together with a little water, when the characteristic odour of rotten eggs will at once proclaim the presence of sulphuretted hydrogen. It can easily be understood, therefore, that the most minute trace of powder of this description present in the pores of the paper would soon produce an injurious effect upon an object so delicate as a photographic print.

There is no doubt, therefore, that the imperfections in question are due to the cause stated above, and the attention of photographers and manufacturers of cardboard is therefore drawn to the subject. Although the consumption of mounts of this description may not be very large, still it will doubtless be interesting to many to know the manner in which photographs may be affected by their use.

## PICTORIAL EFFECT IN PHOTOGRAPHY;

BEING LESSONS IN

COMPOSITION AND CHIAROSCURO FOR PHOTOGRAPHERS.

BY H. P. ROBINSON.

### CHAPTER VII.

"In the study of our art, as in the study of all arts, something is the result of our own observation of nature; something, and that not little, the effect of the example of those who have studied the same nature before us, and who have cultivated before us the same art, with diligence and success."  
—Sir Joshua Reynolds.

HAVING commenced this series of papers with the determination to connect all I have to say on pictorial effect with photography, and to demonstrate the application of the different forms of composition with our art, this seems a proper occasion to give a sketch from a photograph, showing in what manner the rules of art—as far as already expressed—have guided the photographer in the selection of his subject. The sketch on this page gives the leading features of a delicious little photograph of a scene in the

lake district—"Derwentwater, Cats Bells in the distance"—by Mr. Mudd. And I may point out, as a singular instance of the possibility of the photographer moulding his materials to his wishes, the fact that a landscape by Mr. Mudd is rarely to be met with the composition of which is not nearly perfect. From a large collection of his works now before me, I am not able to select more than two or three in which there is felt any want of balance, unity, and harmony; and this small minority consists of local views, or portraits of places interesting from their association, but which do not appear to have been tractable in the hands of the artist. Although the art is properly concealed, the trained eye can discover and admire the many ingenious devices he has adopted to hide a defect, to discover a beauty, or to throw more prominently forward the chief point of his subject. All have admired Mr. Mudd's charming pictures, but few have cared to enquire to what their excellence

was chiefly due, but have been content to attribute it to his perfect manipulation of the collodio-albumen process, a method of working which he has made his own, but which, notwithstanding its excellence, does not account for the skilful arrangement of his subjects. The same remarks are equally true of the pictures of Mr. Bedford. In the works of these gentlemen nothing appears to be done without a purpose. If a figure is introduced, it performs some important function in the composition, either to lead the eye, to emphasize a point, to throw back the distance, or to collect some scattered lights or darks together, by which breadth is gained and confusion avoided. If the point of view admits of a picturesque foreground, whereby an unpictorial principal object may be made into an interesting picture, it is secured; nothing seems to be forgotten that could increase the effect or help to please the eye. And as this occurs in the larger number of views taken by both gentlemen, it

cannot be laid to the account of chance, but must be the result of knowledge.

The sketch gives a very faint idea of the original photograph. It is printed from a photo-type block, by Mr. Griggs, of the India Museum. The relief was taken from a rough sketch, made experimentally to test this process, and sufficient care was not taken to produce a finished drawing, the draughtsman being under the impression that a rather coarse sketch was necessary, instead of which a drawing full of detail would have produced a very much better result. However, the photograph is in the hands of, or has been seen by, so many of my readers that this slight and imperfect sketch will suffice to recall the original to their memories; and I apologise to Mr. Mudd for presenting such an imperfect translation of his beautiful picture.

The first thing that will strike the reader of these lessons as he looks on the original is the admirable way in which balance has been obtained by the boulders in the foreground; the next, the immense distance that is felt between the foreground and the distant mountains. This effect is almost entirely produced by the arrangement and opposition of the dark stones in front. If the stand-point for the camera had been shifted a few feet either to the right or the left, a very different and much less valuable picture would have been produced. The stones in the one case would have been excluded from the picture, and the distance looked flat; in the other, the stones would have been either in the centre or on the right side of the picture, under the dark trees in the middle distance, thus having all the dark on one side of the picture and all the light on the other.

As I am writing, a young friend who has just commenced his study of art by reading "Howard's Sketchers' Manual," tells me the removal of the stones to the other side would produce the "wedge" form of composition, which, he is told, is much used by landscape painters. This is quite true, and agrees with all I have yet said, because all angular composition must, more or less, partake of the form of the wedge, which is the basis of many of the finest compositions. Let the student bear in mind, however, as an axiom, in arranging his masses in this form, *that the point of the wedge must be supported*. Without such support the picture will convey the uncomfortable impression that some of the principal masses will slip down. And I would here guard my readers against the error of my young friend, that of jumping to the hasty and imperfect conclusions which a superficial familiarity with the technical names by which various forms of composition are designated, without an understanding of the principles upon which all pictorial effect must be based. I would strongly recommend the student of these lessons to blend his reading with practice, endeavouring to produce photographs in which art rules are embodied and illustrated. Above all things, avoid the glib parrot-like parade of art terminology, which, without art practice, is such a contemptible thing to all earnest men.

One of the most precious qualities of the photograph that has suggested these remarks is its perfect *expression*. It is not that of repose so much as of perfect serenity. It suggests to the mind one of those lovely days of which not a dozen occur in a twelvemonth, when the sun shines with a *white* light, and the breeze is hushed so still that you can hear the bee hum and the trout leap in the lake,—one of those days when, to the photographer, fortune helps art, but also one of those days on which, with such a photographer as Mr. Mudd, art helps fortune, and is not content with mere unselected looking-glass truth.

I have spoken of the expression of this picture. Some may doubt that such a thing was possible in landscape photography; but it is so, to a very great degree. Some scenes demand that they should be rendered in a sparkling and lively manner; others, such as portraits of places, with all the dry matter-of-fact of mechanical art; others, again, are better expressed under the gloom of approaching twilight. I have before me two photographs: the one so absolutely expresses the effect of early morning that you

feel the chill, bracing air as you look at it. It is difficult to explain how this is obtained. The scene represents the outskirts of a distant town round which runs a river. The distance is composed of hills. The sun shining on the slate roofs of the distant houses causes so many glittering spots of light, which, however, are well grouped together. The river also shimmers in the sunlight, forming a broad curved line of light stretching across and into the picture; the foreground is composed of a steep bank. The photograph in this state would look scattered and without unity; but on the bank is placed the figure of a girl with a basket gathering ferns. The figure is by far the blackest spot in the picture, but possesses touches of the highest lights caused by the strong sunlight, which gathers together and repeats the lights in the distance and on the river. This figure has the effect of reducing the whole into harmony. The conclusion is, that the glittering lights, like sparkling dew, give the effect of early morning, but which, if not corrected, would have a scattered and disagreeable effect, but which is quite compensated for by the figure which brings them into a focus.

The other picture is a view of the pool at Burnham Beeches, in which the effect of the commencement of twilight is perfectly given. The sun is sinking behind a screen of trees, defining the branches and trunks with a thin edge of light. The darkest mass of shadow is in the centre of the picture, relieved by some white ducks on the bank of the pool, and which serve to enliven the only part of the picture that was in danger of dullness. No figure is introduced, and the whole expression is that of solitude and gloom.

In looking over my portfolio I met with another photograph which will illustrate what I have advanced. In this picture, which is by Mr. Durrant, a breezy day is perfectly expressed. It has not that appearance of petrified motion which is sometimes the defect of instantaneous photographs of the sea, but you feel that the wind is stirring the trees, although it is evident that nothing moved while the picture was being taken, and the exposure must have been considerable. The clouds, which are from a separate negative, appear to skim through the sky with a very lively motion. These examples will, I hope, tend to show that photography, even in landscape, need not be the lifeless thing we find it in average productions.

#### M. BRAUN'S COLLODION.

Most photographers are familiar with the charming stereographs of Alpine scenery issued by Mr. Braun, a class of picture in which he has had no rival but Mr. England. Dr. Vogel, in his recent letter to our excellent Philadelphia contemporary, gives the following as the formula of the collodion used, which, our readers will observe, is very similar to that of the collodion generally used by Mr. England. Braun's formula stands as follows:—

##### 1. Iodizer.

Ether	...	...	...	250 grammes
Alcohol	...	...	...	200 "
Iodide of cadmium	...	...	14	"
Bromide of cadmium	...	...	9	"

##### 2. Plain Collodion.

Alcohol	...	...	...	250 grammes
Ether	...	...	...	250 "
Cotton	...	...	...	15 "

1 and 2 are mixed in the given proportions. If the collodion appears too thick, it is diluted with equal parts of alcohol and ether.

##### Silver Bath.

Nitrate of silver	...	...	8 to 10 grammes
Water	...	...	100 "

##### Developer.

Water	...	...	1000 grammes
Protosulphate of iron	...	...	40 "
Acetic acid...	...	...	60 to 80 "

## ACETATE OF LEAD IN THE PRINTING BATH.

At a recent meeting of the Philadelphia Photographic Society, Mr. Newton exhibited some prints which excited much admiration. The process by which they were produced was as follows:—

He floated the paper for half a minute on—

Nitrate of silver	...	...	25 grains
Magnesium	...	...	25 "
Potassium	...	...	25 "
Acetate of lead	...	...	5 "
Water	...	...	1 fl. ounce.

Toned in a bath made as follows:—

Carbonate of lime...	...	1 grain
" magnesium...	...	1 "
" baryta	...	1 "
Water	...	1 fl. ounce.

To which gold was added in quantity sufficient to produce the desired effect.

## A GOOD KEEPING COLLODION.

BY W. J. LAND.\*

HAVING made a series of experiments with a view of ascertaining the best-keeping and most generally useful bromodized collodion, I find the following formula to yield an article which combines, in a high degree, five excellent properties that a negative collodion should possess, viz: great stability and sensitiveness, fine flowing qualities, full intensity, and capability of producing extremely delicate details. This collodion works well when ten days old, and excellently for two years afterward. Samples of the collodion, now twenty-two months old, produce faultless negatives as regards the above-named qualities. It is yet almost colourless, and its sensitiveness scarcely impaired. In working qualities it is very similar to Dr. Vogel's excellent standard collodion, but possessed of greater keeping qualities, which I attribute principally to the bromide of magnesium. It would please me much to have others experiment, and report upon the good qualities claimed for this collodion, which, I believe, is without a superior.

## Formula.

Plain collodion containing	3-5ths
(by volume) of pure alcohol	... 1 ounce
Pure bromide of magnesium	... 3 grains
Pure iodide of cadmium	... 4½ "

The plain collodion used in the experiments was four months old.

## ENLARGING BY MAGNESIUM.

BY J. SOLOMON.†

BEFORE giving you a practical illustration of the method of producing enlarged photographs by means of the combustion of magnesium, a few words on that singular metal may not be out of place.

Magnesium was first discovered by Sir Humphrey Davy, in 1807. He reduced magnesium under the most powerful electric apparatus that had been made in his days. Some years after Mr. Deville obtained the metal by acting on the chlorides of magnesium and ammonium with sodium, but only a few grains were obtained after a troublesome and costly operation.

Bunsen reduced magnesium by decomposing the fused chloride of magnesium by means of the electric battery, and the metal so obtained was pressed into wire. In 1859 Professor Roscoe, of Manchester, instituted some experiments to show the intense nature of the light emitted from combustion of the magnesium, and these experiments were published in 1861.

Sonstadt, of Nottingham, was induced to go into a series of experiments, as it appeared manifest that, if magnesium could be obtained on a large scale and at a reasonable price, it would be a great boon to the art of photography. In the year 1863 Sanstadt patented his process, which is as follows:—

The magnesia of commerce—that is, carbonate of magnesia—is acted on by hydrochloric acid, and chloride of magnesia is formed. To this chloride the chloride of potassium is added, and these are fused together. These in turn are placed in crucibles with sodium, and the magnesium is obtained in small globules, almost as minute as dust. This residue is well washed and placed in a large iron refiner, which is placed in an intensely hot furnace, where it remains from fourteen to eighteen hours, when the metal volatilizes and passes down a tube running through the centre of the refiner, and the metal is found at the bottom in a large lump. It is not yet suited for making wire, because of the impurities it contains; it is therefore broken into small pieces and again refined. Sometimes this refining has to be repeated three times or more, and each time it loses in refining twenty-five per cent. of the metal introduced. The pure metal is cast into ingots, then drawn into wire, and again pressed between hot rollers to make it into ribbon.

Magnesium is the lightest known of all metals, being one-sixth of the weight of silver. It is a very good conductor of heat, and the most energetic generator of electricity known; hence it is now much used instead of zinc for galvanic belts.

Magnesium is mostly known for its lighting properties, and its use and aid to the art of photography is now a fact established. It is used by the army in Abyssinia, and can be attached to balloons, which would prevent any ambush surprise, and can be used as rocket signals, or for lighting up at night the entrance of vessels into a harbour; or for throwing, by the aid of reflectors, its light into the deep sea at night, so that divers can examine the keel or sides of a ship, on an accident happening at night to the lower parts of the vessel. The light is also used in examining the rifled and other cannon, as any trifling crack or flaw is easily distinguished by its means. It is the easiest light for copying oil paintings, giving every shade of colour, producing all the minute shades of half-tone; and an artist is now exploring and taking photographs of everything interesting in the catacombs of Rome.

Having said so much concerning magnesium, allow me to say a few words concerning the magic lantern.

It contains in itself all requisites for producing perfect enlargements of the slides which are inserted, and which for the purpose in hand are in the form of thin sharp negatives. With a good light (such as that of magnesium), a good condenser, and an achromatic object glass (or, more properly, an achromatic portrait combination) what is there to hinder the enlarged image thrown upon the screen from being both sharp and true to all the gradations in the negative? The principle of enlarging is to throw an image upon a screen, which screen shall be composed of sensitive paper, on which, by after-developing or otherwise the image shall be strongly and visibly impressed. For great brilliancy, albuminized paper prepared with iodides and bromides may be employed; or for great softness of design, either rice surface paper or plain paper, such as Hollingsworth, thick Saxe or Rive, can be used. The exciting solution is nitrate of silver, with a few drops of acetic acid added.

The image having been allowed to act on this sensitive paper for a portion of time varying from twenty seconds upon and according to the degree of enlargement required, is afterwards developed by a solution of gallic or pyrogallie acid; and, when the development is considered sufficient, it is fixed by means of hyposulphite of soda. These remarks are only of a general nature. I now proceed to supplement them by actual experiment.

\* Philadelphia Photographer.

† Read before the North London Photographic Association, March 4th, 1868.

## REMOVING VARNISH FROM A COLLODION FILM WITHOUT INJURY.

BY V. G. BLOEDE, CHEMIST.\*

It is often a great desideratum to remove a film of varnish from a negative or positive picture. Not only are many pictures, especially ferrotypes, spoiled by unskilful or careless varnishing, which produces "ridging" on the plate, but the glossy surface of the varnished picture, acting as a powerful reflector, renders the clear and perfect copying of the same impossible. An unvarnished ferrotype can be copied almost, if not quite equal to the original; while one that is protected with a film of any kind of varnish never copies clearly, but always more or less blurred and fogged. Even to the print, a badly varnished, "ridged" negative is, in some cases, highly detrimental. Though, in many cases, very desirable, no process has been hitherto known, as far as we are aware, which would thoroughly remove all adhering varnish, without the total destruction of the collodion film; and in placing before the practical photographer a sure and simple method accomplishing this result, we feel confident that it will prove of much value to him.

Our method of removing the varnish from a picture, and which leaves the delicate film of the collodion cleaner and better than ever, is by means of the vapour of alcohol. Place a small dish or saucer containing about two ounces of alcohol upon a moderately hot stove, and when it begins to boil, hold your picture in a slanting direction, in such a manner that the alcoholic vapour strikes directly upon the film of varnish. Here it is rapidly condensed, and, absorbing the gums, runs off the plate in large drops. In a very few seconds the plate will be perfectly clean, and every atom of the varnish have disappeared, leaving the collodion film in its original delicate condition. The alcohol, in the form of vapour, seems to have a peculiarly powerful action upon the varnish gums, and in this form one ounce is more efficient in removing the gums than when the plate is washed in one pint of warm alcohol. If a large quantity of plates are simultaneously treated, the drippings may be collected, and will generally be found to be of the same consistency as the original varnish used upon the plate. A very convenient way of working this process is with a fuming-box such as is used for fuming or ammoniating silvered paper. A dish of well-heated sand may be placed upon the bottom of the box upon which the alcohol is placed, then, after fastening the plate to the cover of the box in the usual manner, this may be closed. In the course of a few moments the varnish will be found to be entirely removed. Though the sphere of this process is rather limited, it will, nevertheless, undoubtedly find many useful applications.

## Proceedings of Societies.

### NORTH LONDON PHOTOGRAPHIC ASSOCIATION.

The annual meeting of this Society was held in Myddelton Hall on the evening of Wednesday, March 4th, Mr. W. W. KING in the chair.

The minutes of a former meeting having been read and confirmed, the SECRETARY read the following

#### ANNUAL REPORT.

YOUR Committee, on presenting their report for the past year, congratulate the Society on its continued prosperity. Though they cannot but regret that the number of papers has not been so large as could have been desired, yet the following list will show that the session has not been quite devoid of interest in that respect:—

On the producing of diffusion of focus in photographic images, and the effects produced by the use of very small apertures or stops, as required when including a large angle of view—By Thomas Grubb, M.R.I.A.

\* Philadelphia Photographer.

Remarks on landscape photography, and the apparatus employed—By E. Dunmore.

What branches of photography will be found most amusing and interesting to the amateur—By J. Bockett.

Architectural photography—By W. W. King.

Artistic pictures photographically considered—By E. Dunmore.

Glass for photographic purposes, and the changes of colour to which it is subject—By G. Wharton Simpson, M.A.

They would also call attention to the apparatus which various manufactories have kindly exhibited, and especially to the photographs which have been brought before your notice, amongst which, as deserving particular notice, must be mentioned the large photographs of Krupp's steel manufactory, in Prussia, and some exquisite transparencies by Mr. W. Bedford, one subject of which was your presentation picture for last year. It is much to be desired that this branch of photography should be more generally followed up. The surplus, as will be seen by the account submitted by our Treasurer, Mr. Hill, is good, and will enable your Committee to distribute a larger number of prints than they have done in any former year; but they will, as heretofore, however, confine the distribution to that of prints possessing more than average merit, and may point with some degree of satisfaction to what they have done already, *inter alia*, in securing such a beautiful specimen as that of Holy Street Mill, by our member, Mr. Francis Bedford.

In conclusion, your Committee would again urge on the members the importance of the contribution of papers for the meetings, and the exhibition of pictures and apparatus at the same, which always possess an interest for those who are really earnest in photographic pursuits.

The Treasurer's account is as follows:—

#### Treasurer in account with the North London Photographic Association.

Examined,  
JAMES COOPER }  
J. WERGE } Auditors.

4th March, 1868.

D. W. HILL.

The officers for the ensuing year were then elected as follows:—

President: Charles Woodward, F.R.S., J.P.

Vice-Presidents: G. Wharton Simpson, M.A.; W. W. King; A. Goslett.

Treasurer: D. W. Hill.

Honorary Secretary: John Barnett.

Committee: J. Bockett, W. Bedford, C. J. Belton, W. Cooper, E. Dunmore, F. W. Hart, T. Ross, and W. Shave.

It was proposed and carried, after some conversation, that the January meeting, which, coming so early in the month and close upon the time of Christmas festivities, was often inconvenient, should in future be postponed at the discretion of the Committee, who should announce the arrangements made at the December meeting.

Mr. SOLOMON then read a paper on the magnesium light (see page 127) and, with the aid of Mr. Allen, proceeded to demonstrate its value for enlargements, using the apparatus he has devised for the purpose. The exposure given was sixteen seconds, and the enlargement, although good in other respects, was considerably over-exposed.

Some conversation followed, in which Mr. Allen stated that ten seconds' exposure would have been sufficient. The paper was prepared in accordance with the formula we recently described, and developed with a hot solution of gallic acid. Where rapid exposures were for any reason desirable, hot development was an advantage; but for certainty and brilliancy he preferred cold development.

Mr. WERGE exhibited a couple of photographs on albuminized paper, which had been printed about twelve years, and were as pure and fresh in colour as they were on the day they were produced. He attributed their permanency to the method of alternate cold and hot washing which he had recently described at a South London meeting. The subject of one of

the pictures was a charmingly artistic illustration of the "Song of the Shirt," and of the other, "The Sewing Machine."

Mr. DUNMORE exhibited some brilliant prints produced with a concentrated light.

Mr. GOSLETT exhibited several examples of glass which changed in colour from exposure to light.

A conversation on the subject followed, in which Mr. Goslett stated that the common green sheet glass was the least liable to change, and therefore most suitable for glass houses. A 21-ounce glass was of suitable substance.

After some further conversation and several votes of thanks, the proceedings terminated.

#### LONDON PHOTOGRAPHIC SOCIETY.

THE usual monthly meeting of this Society was held in the Architectural Gallery, Conduit Street, on the evening of Tuesday, the 9th inst., the Rev. J. B. READE in the chair.

The minutes of a preceding meeting having been read and confirmed, the Hon. Wm. Petre was elected a member of the Society.

THE CHAIRMAN then read an eloquent extract from a speech intended to have been delivered by the late Sir David Brewster before the Royal Society of Scotland, but, in consequence of the illness which resulted in his death, read for him. It pointed out in forcible terms the value of photography as an adjunct to scientific education, a subject which he (the Chairman) was glad to say occupied much more attention now than it did when he was a boy, for his schoolmaster would at any time have rather have seen him construing a line in Horace on the beauties of the fields, than have seen him gathering or studying the beautiful flowers so described. We shall print Sir David Brewster's remarks in our next.

Dr. MANN then read an interesting account of the difficulties of an amateur in South Africa, and exhibited many interesting landscapes and portraits illustrative of ethnological types. His paper will appear in our next.

Mr. FRANK GOODE said that as he had some experience in photography in the four quarters of the globe, he might offer one or two remarks on the subject of the paper. He was himself a great stickler for the wet process, and did not believe, as a rule, in any necessity for the use of dry plates. He had spent about seven months photographing in the East, and had used it entirely. One of the greatest difficulties which arose consisted in the difficulty of transport of materials, and also of the great heat affecting the chemicals if they were not suitably packed. He had had his packing-cases lined with felt  $2\frac{1}{2}$  inches thick. This was, of course, a somewhat expensive process, but the result was worth the cost, as it kept everything quite cool. His collodion bottles were packed in tin cases surrounded with sawdust. He was from home nine months, and the quality of the collodion steadily improved from the time he commenced using it—two months after he started—to the end of the time. He liked the developer old also, and would, in future, always take care to keep a gallon of developing solution prepared in advance. He had very little time allowed by the dragoman of their party, often having not more than two hours to produce six or eight negatives and unpack and repack all his wet apparatus. Nevertheless, he would use the wet process again. Dry plates would, of course, be occasionally useful for an emergency, where time could not be allowed for getting ready wet apparatus, when the steamer only touched for a short time at any place, but he would rely on the wet for all general purposes.

Mr. S. FRY was glad that Dr. Mann had recognized the importance of getting negatives without after-intensifying, and the advantages which the gelatino-iron developer afforded for such a purpose. In reference to the morphia process his faith had been a little shaken, some plates prepared a few months which he had recently tried having lost sensitiveness almost entirely.

Dr. MANN said, referring to the remarks of Mr. Goode, that no doubt a skilled professional photographer would get good results by almost any process and under any circumstances. It should not be forgotten, however, that photography was more difficult in South Africa than in the desert, as the moisture, as well as the heat, was so troublesome in Africa. His appeal to the members of the Photographic Society was for a process which an amateur might work with some degree of success under the difficult conditions he had described. He should especially have liked to know of any one who had any

experience with the plan of exposing the plate whilst still in the bath.

THE CHAIRMAN, after preposing, in complimentary terms, a vote of thanks to Dr. Mann, announced that Mr. H. P. Robinson had volunteered to produce one of his well-known charming pictures, and present a copy to each member of the Society as a presentation print. Mr. H. Claudet had also volunteered to present each member with a print from the last negative of his late father, which had an especial interest from having been taken with his topaz lens. Mr. England had also promised, when on his summer tour, to produce a special negative for the purpose of presenting copies to the members. These things would prove, in spite of the breezy little notices which appeared now and then announcing that the Society was going down, that its motto was "excelsior," and of this the public, as well as themselves, would become assured.

THE CHAIRMAN called attention to a little work exhibited by Dr. Powell, in which an account of the ascent of the Pieterboth Mountain, in the Mauritius, 2,814 feet high, was illustrated by photographs. He also called attention to some fine specimens of portraiture by Mr. Fradelle. That gentleman, on being appealed to, explained that, having an opportunity of spending a few hours in the studio of M. Salomon, these pictures were the result of an effort to produce results in a similar direction. Mr. Fry exhibited some very fine portraits of a similar class.

THE CHAIRMAN said that the Secretary had received a further communication from Mr. Johnson on the use of permanganate for rectifying the nitrate bath; but as the hour was late and Mr. Johnson was unable to be present, he would defer its reading until another occasion. At the next meeting, also, Mr. Griggs would read a paper on the application of photography to press printing, illustrating the process by demonstration before the members.

After some votes of thanks, the proceedings terminated.

## Correspondence.

### THE COFFEE PROCESS.—RECTIFYING BATHS.

MY DEAR SIR,—I observe, among your Answers to Correspondents, that you hope for some information from me on the subject of the Coffee Process. I confess I have not much more to give than I gave some months ago, the only source of deterioration in negatives lying in the age and failing qualities of the nitrate bath. I have found that by proceeding as I shall presently describe, this fickle fluid may be brought to a state of perfection for the production of negatives, and rendered equal to a new bath, if not superior.

I generally use 16 ounces of bath at a time for 11 by 9 plates, and when this becomes slow and gives hard negatives, I set it aside. After working up some 60 or 80 ounces of solution, I put the whole into a very large porcelain capsule, which I place upon an iron frying-pan filled with sand over the hot plate in the kitchen, and cover the capsule with an inverted glass funnel. I then evaporate rapidly to perfect dryness, and the liquid, which at first was clear and bright, becomes black and discoloured from the precipitation of the organic matter. The salt now froths up violently, filling the whole capsule; nitrous fumes are disengaged; the froth sinks to the bottom; and the nitrate of silver enters into a state of fusion. I keep it thus quietly fused for seven or eight minutes, after which I remove sand-bath and all from the fire, and let it slowly cool. It this is done carefully, the capsule will not crack; but if too much nitrate is left, the salt, in becoming solid, contracts, and adheres so strongly to the porcelain that a fracture will result. When quite cold, I add distilled water, which in a few hours dissolves the salt, and, after filtering, I measure the density of the resulting solution by the argentometer, and add sufficient water to dilute it to 35 grains to the ounce. Then, to every 16 ounces I add one drop of pure nitric acid, which I find quite sufficient to keep the shadows of the negative clear.

If any of your readers will only try this plan—which, after all, involves but little more trouble than the usual system of doctoring a bath—they will find that, with ordinary commercial collodion and an iron developer of 15 grains with 15 minims of acetic acid, first-rate negatives are produced, requiring no after-intensification whatever. As the conditions in this case are unvarying, the result being the production of an absolutely pure solution of nitrate containing a trace of pure

iodide of silver, there seems no reason to suppose that the same very desirable consequences will not always follow from its use. I need not add that the production of satisfactory coffee plates or collodio-albumen plates by Mr. England's method will necessarily follow from the employment of this excellent bath.

Forgive me for the space I have occupied, but the matter is, I think, of sufficient importance to warrant some notice being taken of it.—Faithfully yours,

N. JOCELYN.

Florence, March 2, 1863.

#### PHOTOGRAPHY AND DISEASE.

DEAR SIR,—Your article on "Photography and Disease," and the correspondence thereon, I hope will have the effect of making many photographers take a little more care to guard themselves against the inhalation of noxious fumes and absorption of poisonous solutions. A great many operators and printers are so fearfully careless in the use of the various photographic chemicals that the wonder is we do not hear more of their ill effects. I cannot understand, for instance, why so many will persist in the use of cyanide of potassium. Then, again, citric acid may be in many cases substituted for the volatile acetic acid; the inhalation of the vapour of this acid, I am firmly convinced, is most injurious, used, as it frequently is, day after day in small and ill-ventilated dark rooms. I think, with Mr. Fitt, that the contact of the skin with the solution of nitrate of silver, in print washing, is not so very injurious; but in my opinion the hands should be dipped as little as possible into the gold toning baths. It would be well if all employers would provide their printers with india-rubber gloves\* for use in the operations of toning and fixing. In my time I have toned a considerable quantity of prints, and I have had two or three very painful sores upon the hands. On one occasion I suffered intense pain for a fortnight, and scarcely slept during that time. My general health being remarkably good, I cannot but think that the gold bath was the cause of my sufferings. I should like to know if others have found themselves similarly affected. Perhaps Mr. Bovey could tell us something of the matter.

Your correspondent, M. W. J. S.,† writes of the injurious effects of collodion used for plate cleaning. Why use it? There are other plans to effect this purpose as well.

I consider it as a duty all operators owe themselves to take a brisk walk after work, and so exhale as much as they can of the ether they may have inhaled during the day.

Hoping that this subject may be thoroughly discussed in your pages, I am, dear sir, yours very truly,

Stonehouse, March 9th, 1868.

A PREVENTIVE MAN.

#### PHOTOGRAPHY AND DISEASE.

DEAR SIR,—In your chemical analysis of the compounds used in photography you have always been most willing to lay particulars before the public, and oblige your numerous friends and readers. Would you enlighten my ignorant self the difference in physical strength between an operator and his employer.

I see in your last a correspondent evidently finds out a plan to save his own health by allowing "an assistant" to do the "injurious" part of the work. Does he think employers and employed are made of a different kind of clay? If not, surely his discovery will fail in bestowing much benefit upon his unfortunate fellow-beings who, unlike him, are compelled to work.—I am, dear sir, yours, &c.,

SUFFERER.

March 10th, 1868.

[The question opened by implication in our correspondent's letter is a wide one. He implies that an employer is not justified in paying others to do for him things which would be inconvenient or even injurious to himself. A wide question of social philosophy is involved which we have not space to discuss here; but we may point out that, admitting the principle implied, our correspondent would not be at liberty to employ colliers to hew coals or sailors to reef topsails on a stormy night, or persons to engage in a thousand uncomfortable

or dangerous occupations which conduce to public comfort. To narrow the question to the case of photographic operators, we always urge on employers the importance of securing to their operators the fairest conditions possible for doing their work, such as the use of well-ventilated dark rooms, the disuse of unnecessarily injurious chemicals, &c.; but surely no one would argue for a moment that an employer in delicate health was acting unfairly or selfishly in engaging an assistant to do a certain class of duties for which he personally felt himself unfitted by reason of his delicacy. The portraitist fully engaged in the studio, whether he be employer or employed, has frequently quite sufficient strain upon his nervous system in the duty of managing difficult sitters, without further depressing his energies by the atmosphere of the dark room; whilst the who is fully engaged in the dark room would scarcely be in the best condition for bearing with the whims of sitters, and making artistic pictures of awkward persons.—Ed.]

#### PHOTOGRAPHY AND DISEASE.

DEAR SIR,—I have read with much interest the various letters on "Photography and Disease." It is a very important subject to every photographer, and every person who has anything to say, for or against, should not hesitate to say it, so that our beautiful art may not be condemned unless clearly proved guilty.

The majority of your correspondents seem to hold the opinion that photography is, however practised, unhealthy. That was my own opinion for a long time; but as it was from the first contradicted in my own experience, I have no hesitation in saying that no person has given the matter more careful attention than I have done during the past six years, and I now say without hesitation that I do not believe that photography is in itself more unhealthy than numbers of other professions and businesses that we hear no complaints about. It affords greater facilities for abuse, and is so fascinating that it lures its lovers to over-exertion, and then it receives all the blame.

When I commenced the practice of photography, about six years ago, I had been troubled with a cough for eight or nine years, and knowing that it was considered to be unhealthy, I was naturally anxious in the matter. Being very fond of the art, and determined to learn it thoroughly, you may be sure I did not spare myself; and it rather surprised me when I found that my health was improving. I then concluded that although in general unhealthy, photography was not so to me, and that some of the chemicals did me good. That opinion was confirmed by a medical friend, who, knowing that photography was considered to be unhealthy, felt at a loss to account for my slow but steady improvement in health in any other way than by attributing it to the fumes of cyanide and ether; but he cautioned me as to their dangerous nature. At the time I wrote the particulars to you, and you were so kind as to publish them. That was more than two years ago, and my health still continues better; but I have carefully watched the effects, and now believe that neither cyanide nor ether, nor any other chemicals, affect me, either injuriously or beneficially. The great temptation to over-exertion in summer, and irregularity in taking food, are, I believe, greater enemies to photographers than their chemicals.

As I have done nearly all the work in my business during these six years except print and mount, I have had to do with all the chemicals commonly used; and as I have frequently wrought from six or seven o'clock in the morning sensitizing, printing, and toning, till nine or ten o'clock at night, I had plenty of them.

I know a gentleman who commenced photography believing, with many others, that it was very simple, and that he could make lots of money at it. He did not trouble himself to learn "the reason why" of anything, and knew little about his chemicals. He got tolerably fair negatives, and took a good deal of money; but he lost more than he gained. He mixed his cyanide by guess, and, judging by the manner in which it cleared the negative, I should imagine it could not be weaker than 10 or 12 per cent. of cyanide, and frequently the bottle was left uncorked. He was very careful to have clean hands, and he kept in the kitchen a solution of cyanide for washing them which could not contain less than 12 or 15 per cent. of cyanide. The parlour was above the kitchen, and I have heard his sister say that when sitting in the parlour she could easily smell the cyanide when her brother was washing

\* The employment of horn forceps is best. They are simple, convenient, and clean.—Ed.

† The signature to the letter in our last, "M. W. J. S.," should have been "M. W., Junr." The initials belong to a well-known and highly esteemed amateur of considerable experience.—Ed.

his hands in the kitchen. I could give other instances, but that one is enough of the action of chemicals. And is it, then, any wonder that people suffer?

If photography is so unhealthy, there can be no difficulty in proving it if people come forward; and if not, let all true lovers of the art bestir themselves, and wipe away the stain, and prove that photography is not unhealthy to men of intelligence who know how to use without abusing it.—I am, dear sir, yours very truly,

D. WELCH.

Nevers, March 9th, 1868.

#### MR. HENDERSON'S ENAMEL PROCESS.

SIR,—In your last week's impression of the PHOTOGRAPHIC NEWS you did me the honour of noticing some enamels exhibited by me to a few of the members of the South London Photographic Society. Allow me to make a few remarks concerning the same. My process is in every respect different to any other (as far as I am aware), except that preparations of the same metals are used. By my process I am able to get a great variety of tones, from a blue to red or black. My only difficulty at present lies in my inability to get a suitable material (sufficiently hard) to fire them on. I am experimenting in manufacturing enamel, and hope shortly to overcome this difficulty. Simultaneously with working out my process, I have hit on several useful (if not valuable) discoveries: viz., a permanent printing process on paper without silver, or any white or black surface; a new intensifier; and a more suitable picture for the magic lantern. A transparency (without silver, I say again) can be burned in on glass, and curved, so that when the image is reflected on the screen there will be less (if any) marginal distortion; any density and colour may be obtained.

I am sorry I cannot give the photographic world the benefit of my experiments, for reasons explained before to you. Apologising for troubling you, I remain, sir, yours respectfully,

A. L. HENDERSON.

PS.—I forgot to say that my process is particularly applicable for porcelain, or any glazed surface.

49, King William Street, E.C., March 10, 1868.

[The importance of the incidental discoveries which Mr. Henderson mentions, as well as of his enamel process, will, we are sure, occasion regret to Mr. Henderson himself, as well as to ourselves and to the photographic world, that he cannot with propriety make public the result of his labours. But when a gentleman has devoted much time, thought, and money to the perfecting of any discovery or invention, it is perfectly clear that he is entitled to the advantages of such discovery. We regret to say that the temper in which many discoveries and inventions, when published freely, have been received by portions of the photographic world has not been of a character to induce experimentalists to be content with the scanty and oft-disputed honours of discovery.—ED.]

#### TO TOUCH, OR NOT TO TOUCH.

SIR,—When I read, in the letter on the 106th page of your valuable journal of 28th February last, regarding M. Salomon's portraits—I need not quote the remarks, as I believe there are very few photographers who have not these pages to refer to—I was reminded of some recent experience of my own.

I am a travelling photographer, and having often heard of the great excellence of the photographs of a Mr. Collins, Clonmel, who has acquired at least a provincial celebrity, I, for curiosity, recently visited that town to see the pictures. They far exceeded my expectations, but, to be candid, it appears to me some of them are "touched" and some are not. I must confess, however, I have seen nothing to come up to the general detail and engraving-like softness of these pictures.

But whether these or M. Salomon's portraits, or any others which excel, are touched or not, I feel that professional photographers are sadly in error in condemning a photograph for being "touched" to advantage, as it is a rare occurrence to find one which is not. Many very excellent pictures, as we all know, if left in their original state would be quite objectionable, through spots or lines of a detrimental nature, which will occur with the most cautious and expert manipulator; and if "touching" (as it is called) be a crime, few of us are guiltless. For my own part I am quite incompetent to "touch" in any further degree than is necessary to remove marks or spots; but because

I lack artistic talent, I should consider it very dishonest to condemn what I cannot accomplish. We know that the very best photograph, unaided by the artist's pencil, is often deficient as a work of art. Perhaps, however, it may be foolish to encourage "touching," as its success may prove ruinous in incompetent hands. I know that I have altered the likeness in almost all cases where my ambition tempted me to its practice beyond certain limits, and I fear that we must come to the final conclusion that no photographer can attain the highest excellence in portraiture if he have not something of the skill of a miniature painter.

BONA FIDE.

#### Talk in the Studio.

PHOTO-RELIEF PRINTING.—Mr. Woodbury's process of photo-relief printing has now come into actual commercial operation, and Disderi and Co. are publishing somewhat extensively cabinet portraits of various members of the royal family produced by this means. M. Disderi was summoned a few days ago, by the Prince of Wales, who was desirous of receiving an explanation of the principles and practice of this method of printing.

PHOSPHORESCENT SALTS.—At the meeting of the Chemical Society on Thursday evening, 5th instant, the President exhibited some interesting examples of phosphorescent salts arranged in series so as to imitate the colours in the solar spectrum. A butterfly, also, with gorgeous wings extended, was constructed by placing the various salts, in patches, behind the glass plate of a pressure-frame. These illustrations were the work of M. Gaiffe, and were said to have been prepared from the sulphates of baryta, lime, and other earths, by reduction with carbon to the state of sulphides. They are very similar in character to the series of phosphorescent salts arranged by Prof. Becquerel for the *Conservatoire des Arts et Metiers*, in Paris. To start the phosphorescent activity of the chemical salts the frames were exposed to the intense light given out during the combustion of about six inches of magnesium ribbon.

MORE PIRACY.—Mr. Isidor Gerson, a printseller, of 71, London Wall, was summoned before Sir Robert W. Carden by Mr. Henry Graves, of Pall Mall, the eminent publisher to the Queen, for selling fourteen photographs of engravings of which Mr. Graves possesses the copyright. After some evidence, Mr. Beard took an objection to four of the summonses which referred to the copyrights which charged the defendant with copying "a painting or the design thereof," and urged that there was no evidence to show that these were copies of a painting.—Sir Robert W. Carden reminded Mr. Beard that the words were "or the design thereof."—Mr. Beard contended they were the same thing. With regard to the other summonses, they were for fraudulently selling photographs with the name of a person on them as the maker who was not the maker. There had been no evidence of fraud, and without that there could be no conviction. If, however, the worthy magistrate decided on convicting defendant, he hoped Sir Robert W. Carden would grant him a case.—Sir Robert W. Carden said that it was impossible to believe that there was not a guilty knowledge on the part of the defendant. He would not fine him the full penalty of £10 in each case, but in the mitigated penalty of £5, or one week's imprisonment in each case, making £70 or fourteen weeks' imprisonment. In France it would be imprisonment without a fine; he trusted he should see the time when that would be the law in England.—The fines were then paid under protest.

PENSION TO LADY BREWSTER.—A pension of £200 per annum has been conferred on Lady Brewster by the Government, in consideration of the scientific labours of her husband.

PATENT LAW REFORM.—At a recent meeting of the Inventors' Institute, on Thursday last, Mr. R. Marsden Latham read a paper "On the Desirability of Assimilating our Patent Laws to those of France and America, to enable this Country to Maintain its hitherto almost Uncontested Superiority in the Mechanical and Chemical Arts." After some discussion, the further consideration of the subject was postponed until the next meeting.

VIGNETTING IN THE CAMERA.—Various methods have been employed for the purpose of vignetting the negative so as to

secure uniformity and save trouble in printing. Mr. Rejlander mentioned to us, a few days ago, a plan which he had been using with success. A piece of card, with a suitable aperture, is placed in the camera, an inch or two in front of the sensitive plate, which was then duly exposed to the object to be taken, the image, of course, being vignettied by the card in the camera. The edge of the plate would, however, be transparent, and if used so would yield a vignette graduating into black instead of into white. The next operation is therefore to place in the camera, in place of the card, a piece of glass or mica, with the centre blackened and rendered opaque to protect the image already received on the sensitive plate. The margin, being then exposed to light, becomes, on development, dense and opaque, and produces a satisfactorily vignettied negative.

## To Correspondents.

**DELTA.**—For new plates we generally prefer the use of a cream or paste of alcohol and rotten-stone. Water and rotten-stone, or water and whiting, will, however, answer. For plates which have been used, dilute nitric acid is good, or a cream-like solution of whiting and water, with about half a drachm of cyanide of potassium added to each ounce. 2. Permanganate of silver will render almost any sample of water sufficiently pure for all photographic purposes. It is not an article kept in commerce. No doubt such a firm as Messrs. Hopkin and Williams will prepare it for you. 3. Red blotting-paper pressed in contact with the back of the plate will, we believe, serve. Mr. Gordon uses burnt sienna, we believe. This is kept in a moist state, and applied with a broad brush.

**VENATOR.**—You had better have glass on both sides of such a studio as that you describe. The amount of glass you describe will probably serve. 2. The lens you propose to use is scarcely sufficiently long enough in focus for cabinet portraits; but used with a small stop it will serve. It is the only lens we know which is so well suited for producing both cards and cabinets. A studio of 27 feet long will answer. 3. We shall be glad to see the plate-box. 4. We shall have pleasure in showing you the Salomon portraits if you call at our residence. Wednesday you will certainly find us at home.

**W. J. A. G.**—Of course the tent will be kept accessible to fresh air when not in use; but we should also prefer, with a perfectly waterproof covering, to have a means of admitting air whilst operating. Five or ten minutes, a period sometimes necessary, in a small tent in hot weather, with the fumes of chemicals, render ventilation desirable. As to the mode of admitting air without admitting light, you have only to remember that air will turn round any number of corners, and that light will not, to devise a satisfactory means of ventilation. An aperture underneath the table part of your tent will serve; or an aperture anywhere, covered with a loose apron. In some tents a ventilator is placed underneath the small tank which stands on the top of the tent. 2. Although, with some forms of bellows camera, you can get some of the advantages of the swing-back, you cannot get all, nor can you get them so perfectly or so conveniently. You could not, by keeping the front portion of the camera level, and tilting the part containing the plate, obtain the advantages of the swing-back. The principle to be remembered in getting correct images of buildings, &c., and avoiding converging uprights, &c., is that the plane of delineation (that is, the sensitive plate) must be parallel to the building to be delineated. 3. The instrument you mention was good eight or ten years ago, but has since been superseded by better instruments. 4. For the purpose you describe we should select No. 3.

**OLD SUBSCRIBER B. B.**—Gum Regialine is an American preparation, sold for the purpose of mounting photographs ready for use. Of its nature or qualities we have no information.

**G. Y.**—There is only one work published on the subject of photolithography or photo-zincography; that is the work of Col. Sir H. James, published by Messrs. Longman at 12s. 6d. It does not enter into minute technical details of the process.

**F. W. P. (Chelmsford).**—Mr. Morley, of Islington Green, whose announcement you will find in our advertisement pages, is the most likely.

**Q. Y.**—Primarily, the collodion you use is not the best suited to the purpose of transferring. It has not sufficient body, and does not give a tough, tenacious film. The wax should be rubbed off the plate, but still a thin and almost imperceptible film should be left on. The addition of a few drops of a saturated solution of wax in ether added to an ounce of collodion will facilitate the transfer. From your letter we glean that you apply the gelatine to the collodion film. This is not right. You should

have gelatinized paper ready for use, which should be applied to the wet film and pressed in contact. If the gelatine be applied warm to the plate it will sometimes permeate a porous collodion, and make it difficult to transfer; but the gelatine on paper merely becomes adhesive by contact with cold water, and could not permeate the film. We have recommended the use of plain gelatinized paper for the purpose of getting rid of the high glaze which you seem anxious to secure. To secure this in its perfection you should use the enamelled paper prepared in France expressly for the purpose, and which is sold ready for applying to the wet film without further preparation. The wet method of transfer is the simplest, but if you prefer the dry you may facilitate the transfer by adding a little alcohol to the water in which you immerse the plate before stripping. The plate you sent to us we immersed for an hour in warm water, and removed the film without difficulty, but found that the film was not very suitable. The printing and toning were good. The card you send is an albuminized print treated with gelatine and collodion, or "enamelled," as it is termed, in the manner we have often described. Those of Disderi's are, on the contrary, camera-printed images on collodion, transferred to the French enamel card or paper—to which we have just referred—and then mounted in the ordinary way.

**E. KENYON.**—Mr. Hart, whose address you will find in our advertising columns, will, we believe, supply them. 2. A clean, thin, delicate transparency is necessary for the lantern when a weak light is used, and the weaker the light the more clean and delicate the transparency should be; but there is no special mode of producing transparencies suitable for lamps with weak light. 3. Read the article on Double Printing in our YEAR-BOOK for 1864. Where an object projecting into the sky is large, it is necessary to cut a mask to fit it; but in case of flag-staffs and similar objects, you may print your cloud negatives over them without danger.

**D. G. (Fews).**—Your question is scarcely quite clear. You ask why the albumen leaves the paper after toning, and refer us to the card enclosed as an example; but the card affords us no evidence that the albumen has left the paper, as it possesses an even, good surface, although not very highly glazed or albuminized. Possibly you mean that the surface of the finished print is not as highly albuminized as the original paper. Such a thing may happen from two causes: either the use of a nitrate bath deficient in silver, or too short floating on a strong nitrate bath. In either case the whole of the albumen film is not perfectly coagulated, and a portion of it is dissolved in the subsequent operations of toning, fixing, and washing. The lighting and general qualities of the card are pretty good.

**R. S.**—The edges should be turned up, so as to make a dish of the picture, and the gallic acid solution poured in. 2. After developing wash well, and then fix in hypo in the usual way.

**H. W.**—We have not ourselves tried the chloride of lithium or tartaric acid in the collodio-chloride of silver process, having had difficulty in getting good results with our own formulae. The chloride of strontium we prefer, and citric acid. See our last YEAR-BOOK. If you use chloride of lithium, little more than half the proportion necessary of the strontium salt must be used. Tartaric acid may be substituted for the same quantity of citric acid. The formula mentioned is suitable for paper or glass. 2. Vigour and depth depend partly on the presence of free nitrate, and on the presence of citric acid; and also somewhat on having plenty of body in the collodion. 3. The chloride of calcium for drying purposes may be dried in an oven.

**BETA.**—We will give you our best opinion when the specimen arrives.

**PHOTOTYPES.**—We have received from some correspondent two examples of phototype prints, from pen-and-ink sketches, but no advice or memorandum concerning them.

**H. S.**—See notes on the rectification of your bath on another page.

**J. L.**—The name is, as you suppose, merely one of the many aliases of the same person. It is not of sufficient interest to be worth exposing.

**HYPO(CHLORHYDRIAC)** has not sent us his name in confidence.

Several articles in type are compelled to stand over until our next.

Several Correspondents in our next.

## THE USE OF COMMON WATER IN PHOTOGRAPHY.

THE use of distilled water in photography, especially for the nitrate bath and some other purposes, has so long been held as one of the most sacred canons of the art, that any suggestion to supersede it by the use of common water is regarded by many as rank and dangerous heresy. In a correspondence which has appeared in our columns during the course of the last few weeks this question has been discussed, Mr. Nelson Cherrill taking the initiative in advocating the disuse of distilled water and the use of common water for all photographic purposes. In this recommendation he is joined by some others, especially by a photographer so capable and experienced as Mr. Russell Sedgfield, who states that for many years past he has abandoned the use of distilled water in all his photographic operations.

If distilled water always meant pure water, and secured the immunity from the troubles which impurities in the bath engender, the mere question of its slight additional expense would be scarcely worthy of consideration, and we should be indisposed to entertain any suggestion for its abandonment; but it unfortunately happens, as the experience of too many photographers bears witness, that distilled water is frequently not pure water, and that fog and other defects in a new bath, which have caused weeks of trouble, have, after an exhaustive process of searching, been traced to the distilled water of which the bath was made. Dr. Anthony, in our YEAR-BOOK for 1867, pointed out the difficulty in obtaining distilled water free from organic contamination: the use of the same apparatus for distilling essential oils and distilled water, carelessness as to the luting, and a variety of other causes, tending to the impurity of the water even when distilled purposely; whilst the use of the water condensed from waste steam is another fertile source of trouble in what is supposed to be pure water.

Seeing, then, that distilled water is too frequently impure, and is often an unsuspected source of fog, it becomes worth while to enquire whether it cannot be dispensed with altogether. In suggesting the use of common water, the first difficulty which arises is the indefiniteness of the term and the variability of the substance. The meaning the term is intended to convey is the water in common use for domestic purposes, such as drinking, cooking, and lavation. This, of course, is derived from various sources, and is of very variable quality. In most large towns in the present day there is a water supply from some river or lake; in some cases it is obtained from wells; and in a few instances from the rainfall. In all these cases it is certain to contain more or less of organic contamination; and in the two first cases the water generally contains in solution various inorganic bodies, chiefly chlorides and carbonates. In London the water supplied by the different water companies varies a

little in quality, but contains an average of from 17 to 20 grains per gallon of inorganic matter (chiefly chloride and carbonate, calcium generally furnishing the base), and from 2 to 3 grains of organic matter per gallon.

As a general rule, these substances can be easily removed by the action of light and oxide of silver. Half a dozen years ago, Mr. Barter, at the North London Society, expressed a conviction that if a nitrate bath were rendered alkaline and sunned before use, it did not matter whether it was made of distilled water or not. At the same time he exhibited various examples of distilled water to which he had added one grain per ounce of nitrate of silver, and then exposed them to light. In all cases they exhibited the presence of organic matter.

Incidentally, he pointed out the importance of rendering the weak silver solution alkaline before exposing it to the light: a sample rendered alkaline and exposed to light had precipitated its organic matter and become clear; another sample, rendered just neutral, and exposed during the same time, had become black and turbid; whilst an acid sample, under similar treatment, became discoloured under the action of light, but gave no precipitate.

With the water of the New River Company, in London, we have for years made printing baths, and have never experienced any difficulty, and with the same water we have, adding a grain or two of nitrate of silver per ounce and sunning, made a negative bath which worked well. Mr. England informs us that in his last summer's tour, in which he worked only dry plates, he rarely used distilled water for washing them, the water accessible in the majority of instances being rain water. Mr. Mudd remarks that in his dry plate operations he never uses distilled water for washing. Mr. S. Fry has for many years, and in different parts of the country having different qualities of water, used only common water for the preparation of the printing bath, and has derived the positive advantage of preserving the solution from becoming discoloured. We might multiply examples in which the disuse of distilled water, for all purposes but the preparation of the negative bath, had been attended by success, if any good purpose could be served by enforcing the argument.

But our chief purpose is to point out that one of two courses is desirable in regard to water. The photographer should distil water for himself, or resort invariably to some means of purifying the water distilled or otherwise, before employing it for a negative bath. An intelligent correspondent—who, in reply to Mr. Cherrill, strongly enforces the importance of using distilled water, and speaks of the certainty to be derived from its use—explains the satisfaction it has afforded him, by mentioning the fact that he distils for himself. Photographers who purchase distilled water should, before making a nitrate bath with it, either add about a grain of nitrate of silver to each ounce, with

sufficient caustic potash to render it alkaline, and then sun it; or add a trace of permanganate of potash to it. In either case they oxidize and get rid of the organic contaminations so commonly present, and secure pure water for the bath. This might be done with a stock of water in advance, and would generally save the subsequent trouble, too frequently necessary, of sunning a new bath before satisfactory results can be obtained.

The second course is perhaps simpler, and will be found, we believe, as efficient; but it involves the heresy of discarding distilled water. Since the latter will generally require purifying before it can be used with safety, it is just as easy to begin by purifying common water. This may be effected by means of permanganate of silver, which will remove at once both organic and inorganic impurities, and yield the much desiderated article—pure water. Permanganate of silver is not at present an article in commerce, but will doubtless soon become so if a demand for it should arise. Those of our readers accustomed to chemical manipulations may easily prepare it for themselves, by mixing warm solutions of permanganate of potash and nitrate of silver in equivalent proportions,\* and, on cooling, the permanganate of silver will separate in needle-like bronze-coloured crystals. This will be found to be soluble in the proportion of 4 grains to an ounce. The purple solution added to common water, a little at a time, until it ceases to lose colour, will effect the purification required.

#### PHOTOGRAPHIC EXHIBITIONS IN LONDON.

THERE are, at the present moment, three or four exhibitions of photographs in London which, although not extensive, are interesting, and will repay the trouble of a visit from those of our readers who have opportunity.

At Colnaghi's, at the West End of London, and at Leggatt and Hayward's Gallery, in the East, may be seen an extensive collection of carbon prints, produced by Braun, of Dornach, by Swan's process. They consist of reproductions of the drawings of the most famous of the old masters, which are found in the Louvre at Paris, and the galleries of Vienna, Florence, and other continental cities. Many of these are from studies in red chalk, *sepia*, &c., and are, in each, reproduced in facsimile, and are, in many cases, undistinguishable from the originals. Of the beauty of these results, and the inestimable value of this process for multiplying and perpetuating the rare and, in many instances, the already perishing drawings of the grand old masters, we have often spoken, and need not dwell on the subject now. We rejoice to know that, by the operation of a company now in the course of formation, the same permanent reduplicating process will shortly be performed for the almost unknown art-treasures at present buried in the British Museum, and other collections in this country. One of the most important applications of photography, the popularization of works of fine art, has hitherto been almost overlooked, if not quite neglected, in England. It is satisfactory to know that, now that it will be commenced in earnest, a permanent printing process will be employed in effecting it. In the meantime, we recommend our readers to form an idea of the importance of such a project by visiting either the exhibition in Cornhill or Pall Mall now open.

At the German Gallery in Bond Street, Mrs. Cameron exhibits a very extensive collection of her studies and portraits. Our own opinion on this style of work has been already recorded. There is, in many cases, much evidence of art feeling, especially in the light and shade, the composition, so far as form is concerned, often being awkward. The subjects of many of the portraits—such as Sir John Herschel, Henry Taylor, Holman Hunt, Alfred Tennyson, and others—are full of interest in themselves, and are often noble in form and appearance, a circumstance which alone gives a value to the exhibition. Not even the distinguished

character of some of the heads serve, however, to redeem the result of wilfully imperfect photography from being altogether repulsive: one portrait of the Poet Laureate presents him in a guise which would be sufficient to convict him, if he were charged as a rogue and vagabond, before any bench of magistrates in the kingdom.

The attempt at the Crystal Palace to reproduce, in instalments, the best portion of the British display exhibited in Paris last year, can scarcely be called a success. Of the photographic contributors, only five put in an appearance at Sydenham. Mr. Blanchard exhibits some large heads and portrait studies, which have very fine qualities. In addition to the Zealot and a Praying Monk, which were in Paris, there are some large heads with much of the old-master-like effect—to coin a phrase—of Mrs. Cameron's productions, without the slovenliness of execution. A head of Mr. Blanchard himself is very fine, round, rich, and finely modelled. Some other heads are characterized by the same massiveness and force. Mr. England exhibits a number of his charming Swiss views, in which it is interesting to note that those produced from dry-plate negatives are absolutely a little softer and more delicate than the prints from wet-collodion negatives. Mr. Pouncy exhibits carbon prints on paper, canvas, and wood, of various degrees of excellence, some of them being exceedingly good. M. Adolphe Beau has some fine portraits, possessing much art excellence. Messrs. Caldesi exhibit some interesting medallion portraits, in which the portrait is surrounded by a name or description, produced on the medallion by double printing, in the manner described some time ago in our pages.

#### PHOTOGRAPHY IN SOUTH AFRICA.

IN Dr. Maun's interesting record of the difficulties of an amateur in practising photography in South Africa, which will be found on another page, there are two or three experiences which suggest a word or two of comment.

One of the circumstances recorded, as stated, appears sufficiently startling, especially when regarded in the relation to canons which at one time prevailed in relation to the nitrate bath. He describes the extraordinary success of a friend who was in the habit of pouring nitric acid into his bath in an unmeasured stream, "revelling in a nitric acid sea of unknown and unguessed depth." As we fancied on listening to the narrative, we found, on subsequent inquiry, the doctor's friend used in this bath a collodion containing a large proportion of a bromide. The nitric acid, which, used in conjunction with a simply iodized collodion, or one containing only a trace of a bromide, would produce total insensitiveness, with a freely bromized collodion not only secures cleanliness, but permits a very high degree of sensitiveness. We do not here enter into the *rationale* of the question, but simply recall the fact too little known, or frequently forgotten. The fine, large, instantaneous pictures of Colonel Stuart Wortley were produced in a nitrate bath containing from two to three drops of nitric acid in each ounce of nitrate solution; and the collodion employed contained not less than two grains of a bromide in each ounce of collodion. A thin, delicate, fully-detailed image was obtained with these materials, with very short exposure, the requisite vigour being secured by subsequent intensifying. We refer those interested for further details to the paper of Colonel Stuart Wortley, which appears in the *Photographic News*, vol. vii., p. 76.

Another difficulty referred to by Dr. Mann is the rapid glutinizing of the collodion by the evaporation of the solvents, which was not got rid of by the addition of fresh alcohol and ether. This the doctor refers to certain improvements introduced into the manufacture of collodion some eight years ago, as anterior to that period he never experienced such troubles. The "improvements" here referred to consist, probably, in the more common use of cadmium salts in collodion, which tend, especially with some samples

\* 170 grains of nitrate of silver to 158 grains of permanganate of potash.

of pyroxyline, to gelatinize the collodion and render it unmanageable if used too thick. In the use of cadmium salt<sup>s</sup> there is at times a balance of advantages and disadvantages: whilst they render the collodion more stable, and preserve sensitiveness, they also tend, if used with a pyroxyline yielding a horny film, especially when newly mixed, to glutinize the collodion, rendering it difficult to coat a large plate without producing a lumpy, uneven layer. There are two remedies for this: the use of a pyroxyline made at a high temperature, and somewhat dilute acids, which yields a limpid collodion, the physical properties of which are not so readily injured by the cadmium; or adopting the practice of Mr. England, whose collodion is generally mixed at least a twelvemonth before it is used. The addition of a portion of an alkaline iodizer is, of course, valuable in checking this tendency to glutinosity in the collodion; and when brouides are freely used, a collodion so prepared will preserve its sensitiveness for many months, even at the high temperature of the tropics.

Probably, for amateur purposes, a good dry process, such as Mr. England's, would involve the fewest difficulties. The plates could be prepared in the evening when temperature is cool, and as many days in advance as by experience the plate may be found to keep perfect. The impedimenta of the tourist would be thus reduced to a minimum, and, whilst his anxieties and risks would be materially reduced, his attention could be solely devoted to the selection of his subject. The plan adopted by Professor Piazzi Smyth, of exposing the plate whilst in the bath, scarcely seems adapted to meet the difficulties described. If it be difficult to get a film free from lumpiness on the one hand, and reticulation on the other, it is clear that negatives possessing such physical defects will yield but sorry enlargements.

#### PHOTOGRAPHIC PIRACY.

THE meanness and immorality of piracy are so manifest to simple-minded, honest men, that it should seem something like a waste of words to enter into discussion to prove its iniquity. When one man has expended time, thought, and money in giving embodiment to an idea of which he hopes to reap the profit to be derived from introducing it to the public, it cannot require argument to prove the dishonesty of him who filches that idea, and deprives its owner of his legitimate profit. Nevertheless, it is possible to surround the subject with complications sufficient to bewilder the thoughtless, and to enable the dishonest to urge some specious pleas in justification of their mal-practices. We ignore the plea of public utility which has been put forward, inasmuch as it is perfectly clear that public utility can never be served by private wrong. But it was at one time plausibly urged that where publishers of engravings had, for the purpose of increasing their own gains, neglected to comply with the conditions upon which the law guaranteed them protection, they had practically surrendered their copyrights, and given the public a right to take possession of that which had virtually become common property.

In the recent cases at the Guildhall, in which conviction has been followed by heavy penalties, there were, however, neither complicating nor extenuating circumstances. Well-known copyright engravings, in regard to which all the requirements to secure legal protection had been satisfied, were extensively and knowingly pirated, and the penalty inflicted was most richly merited. Nevertheless, if the statements of an esteemed contemporary are correct, there are circumstances connected with the mode of detection which are calculated somewhat to lessen the sympathy with the grievously wronged prosecutor. The *Stationer* complains of a system in which the unwary, and possibly the ignorant, are entrapped into breaches of the law by the artifices of hired informers whose sole object is to secure a conviction. We quote at some length from our contemporary:—

"Mr. Graves is perfectly justified in protecting his rights,

but we do not like the spy system he has established. Such a principle is thoroughly at variance with English notions, and ought not to be countenanced. Persons who are willing to try to entrap others into committing an offence are themselves morally guilty. Indeed, they are a nuisance to society, and cannot be styled respectable members of it. We do not assert that Mr. Graves has ordered his myrmidons to resort to underhand ways to detect offenders against the law of copyright; but we opine that any man who will permit himself to follow the occupation of a hired informer is an individual who will not be over-scrupulous as to the means he employs to attain his end. *Apropos* of this, we know instances where *quasi* customers have called upon vendors of photographic scraps, and urgently asked them to procure certain copyright pictures. A few days after their proposal has been made a stranger has opportunely called upon the dealer, and offered some of the precise photographs that were required. He has asserted that he is in pecuniary difficulties, and must realise his stock at any sacrifice. Tempted by the favourable terms of purchase, and feeling compassion for the assumed wretchedness of the traveller, hawker, or whatever he may be, the shopkeeper makes a random bid, which in the end is accepted. Again the customer calls, and expresses his great desire to possess the copies previously asked for. In an unguarded moment the dealer exhibits his illegal purchase, makes an illegal sale, and so brings himself within the meshes of the law. This is no isolated case; and though we cannot assume that there has been collusion or conspiracy between the impecunious man and the lavish customer, it is not without the range of probability. It is therefore possible that some of the prosecutions instituted may have had their origin from such circumstances as are above indicated, though we acquit Mr. Graves from being a party to such proceedings. That gentleman is a patron of high art, and expends his money with a lavish hand. It is therefore a duty he owes to himself to protect his interests, though we fail to see what pecuniary loss he sustains in the individual transaction when one of his own servants buys for his own use copies of his own works. The loss can only be a presumptive one, founded on the idea that other copies have got into circulation. In the prosecutions referred to several months were allowed to elapse before proceedings were instituted; and in permitting such an interregnum to occur we consider Mr. Graves to have committed an error. Having in view the ruinous effects of dealing in copyright photographs, we hope that our subscribers will refrain from dealing in such contraband ware. And they must bear in mind that the number of prosecutions which are reported in the papers do not represent the whole of the proceedings that are instituted, inasmuch as many actions have been privately settled. It is also well they should know that not only are they liable to be fined, but they also lay themselves open to a civil action for damages. The law, therefore, permits them to be doubly amerced for the commission of one offence, than which there cannot be a more unjust enactment. To punish a man twice for the same offence is not in accordance with our national views of jurisprudence, and the law which allows it should be repealed."

In reference to the last remark, it must be borne in mind that the punishments permitted are of a widely different nature, and can scarcely in both cases be regarded as punishments inflicted by the law. The law inflicts a penalty for a breach of its own provisions. But besides breaking the law, the pirate robs the owner of the copyright of a portion of his profits, and the law permits him, on proving his injury, to recover damages to such extent as he can show that he has suffered. His interest in the penalty may very inadequately recoup him for his losses, and surely there is nothing unfair that the honest trader should receive compensation for his losses to the fullest extent they can be proved to exist. Further, if piracy can be made unprofitable, it will soon cease to be practised.

In regard to the employment of informers, we hope that

Mr. Graves and others in his position neither instigate nor encourage such a system; for whilst they have suffered grievous and irritating wrong, the use of such vile tools will scarcely secure a remedy, or, at any rate, not without risking much injury. The informer's net will probably secure shoals of the ignorant, unwary, and comparatively innocent dealers, whilst the greatest and most cunning offenders will escape scot free. In the recent cases there can be little doubt that the offenders risked the penalties with their eyes open, and no sympathy need be wasted on them on the score of being entrapped into the offences of which they were convicted.

## PICTORIAL EFFECT IN PHOTOGRAPHY;

BEING LESSONS IN  
COMPOSITION AND CHIAROSCURA FOR PHOTOGRAPHERS.

BY H. P. ROBINSON.

### CHAPTER VIII.

"What is beautiful must be decided by each man for himself and at his peril. There are some who maintain that all nature is beautiful. Fortunately, we can now disprove this monstrous position by our daily experience of photographs. Even if they were quite true in effect, form, or expression, they would often be none the less ugly. They are usually planned and made by men of some chemical knowledge, but tasteless and entirely unacquainted with fine art. Consequently, the photographers unconsciously offer us the mean and ugly mixed up with some beauty."

*Fine Art Quarterly Review.*

COMPOSITION based on the diagonal line—the form of arrangement to which the foregoing chapters have been principally devoted—having been considered, it appears to be a fit time to say something on landscape composition generally, the more so, seeing that I have already urged the student to accompany his study of these lessons by practical attempts to carry out the instructions from time to time brought under his attention. A few hints on his general mode of procedure in attempting landscape work may, therefore, be of service here.

Elegance in landscape composition, in views where no extraordinary object suffices in itself to engage the attention, appears to demand free sweeps of lines contrasting each other; a fine vigorous foreground, which—especially in photography—should be made use of to govern and correct those parts of the picture which are beyond the control of the artist; a middle distance that delicately melts into the distant mountains and into the sky. Lines, and light and shade should be so arranged that the eye is led into the picture and allowed something to rest upon; that something should be the *theme* on which the picture is built. If there are any ugly lines in the view that cannot be got rid of by change of position, or by opposing lines, or masses of light or shadow in the foreground, then the background of the landscape—the sky—must be made use of, and, by the disposition of the clouds, much bad composition may be remedied.

There are several things worthy of the careful consideration of the landscape photographer before he packs up his traps and takes the field. The first is a meteorological one.

Without a favourable state of the weather, the most perfect manipulation and skilful arrangement would be worse than useless; they would be thrown away upon subjects that might have been better done under more propitious circumstances. Nothing is more annoying to a conscientious photographer than to know that a greater degree of perfection might have been attained than that which he has effected, except, perhaps, the possession of a negative too good to destroy, but not good enough to print—a negative just so much short of perfection as to cause regret that it ever was done.

The most perfect day for pure landscape operations is one on which the wind is still; and when I say pure landscape I do not include sea-views, which are, perhaps, more grand, if not more beautiful, under the influence of wind than in a placid condition. It has been said that nature is insipid when in a quiescent state, and that it would be better to sacrifice

sharpness than to tolerate tameness; but, apart from all photographic considerations, what can be more beautiful than the majestic calm of a still landscape? The great charm of a fine twilight consists more in the serenity and quietude that reign at that period of the day when—

"All the air a solemn stillness holds,"

than in the fading light and in the dying of the day. Incidentally, another fine effect of contrast may be here mentioned. Who, when taking an evening walk in the country, has not felt the effect of the twilight calm increased and enhanced by the sudden sound of the slamming of a distant gate, or the bark of a dog in a neighbouring farmyard?

Of all faults photographs possess as pictures, that caused by the motion of the object photographed is one of the worst. This is especially true of foliage; and if a negative is found to have this defect to any degree, it should be rubbed out at once. Still waters, as a rule, are best on quiet days. Gusts of wind partially skimming over a lake adds surface to the water and vivacity and life to a picture, it is true, but there is great beauty in the grand reflections in still water, which is so exquisitely rendered by our art.

The light, usually held to be of the first consideration in photography, is here placed second, because if the subject be not in a fit condition to be photographed, it would be useless to have it well lighted. It should be taken as an axiom that most landscape subjects should be sun-lighted. Nature certainly looks more beautiful in sunlight than in shade (there are, of course, exceptions). A landscape without sunlight, especially if it be an extensive view, is usually flat and low in tone, and this tameness would certainly not be lessened in the photographic transcript, for if a subject have not sufficient breadth of light and shade to give relief, the landscape photographer's powers of producing that desirable quality are very limited, and the attempts to do so generally result in hardness; besides, who would prefer the cold, dull, prosaic effect of daylight to the warm, cheering glow of "nature's smile."

In selecting a sunny day it is not necessary that a cloudless sky should be chosen; on the contrary, a dark blue sky is very non-actinic, and a day on which white clouds float lazily over the heavens, occasionally obscuring the sun, a day that often comes after rain, when nature looks fresh and cheerful, is the best that could be chosen for landscape photography.

The choice of a subject is the next thing that should claim the attention of the photographer; and now will be the time when the student will show his capability in artistic treatment. Here let me earnestly entreat the student to follow my advice in one thing: let him determine to be content at first with one subject; to work at it with all his heart and soul until he has got the best possible representation of it. Even if it take a summer, let him determine to produce a masterpiece. A complete triumph over one subject is worth more, both as a study and as a picture, than the indiscriminate picking up of any quantity of dull and feeble commonplaces. If a lot of mere photographs are wanted, it is better to send a man to manufacture them; it will be found much cheaper also; but the study necessary for the production of a perfect photographic landscape is worthy of the attention of a superior intellect.

Now comes the question how to produce this masterpiece.

It is of no use taking a camera with you the first time you visit unknown ground in search of subjects. When you have selected your subject, and are satisfied it will make a good picture, let it command your individual attention. Consider it as a painter would, if he were going to make a large and important picture of the scene; consider the best time of day; visit it several times during the day to notice how the changing position of the sun alters the light and shade and shape of the masses. It is too often the practice of photographers to work with the sun behind the camera, so as to get all the light possible on the subject, forgetting that it is not light alone that they want, but light and shade. The charm of sunlight depends very much upon aspect. This

must be carefully considered by the student. Some subjects are better with the sun coming from the side, and others with the sun more behind the view, skimming the edges of objects only with its rays. Having chosen the subject, then fix the exact spot for your point of view; this will give you less to think of when you bring your camera next day. Remove any obtrusive boughs that appear likely to interfere with the view. And, lastly, think if there is anything you could do to improve the already well-considered composition. Make up your mind if a dark or light spot is required in the foreground to give balance, and if a figure would answer the purpose, and what kind of figure, bearing in mind that broadcloth and black hats are no improvement to a country landscape, and that harmony between animate and inanimate nature must be imperatively preserved.

When you are perfectly satisfied that your view presents the best possible aspect, that you have your figures and all else quite ready, you may begin to think of your chemicals, which I would rather you consider as your tools, over which you have perfect command, rather than as a series of scientific problems on which you are about to make experiments.

There are other considerations which I intended to include in this chapter, but I have filled my space, and must reserve them for the next.

### SOME FURTHER EXPERIENCE WITH HYPOSULPHITE OF AMMONIA IN THE TONING AND FIXING BATH.

BY NELSON K. CHERILL.

As I mentioned in my paper on the use of Hyposulphite of Ammonia (published on the 7th of February) that I proposed to continue my experiments with that substance, and that should any further successful results be obtained I would send a further communication on the subject, so now I intend to do. I have, since the publication of my former paper, continued my experiments with much success; and, having a few more observations to make on the use of hyposulphite of ammonia, I think it time to send some illustrations of the progress made up to this time.

In the first place, I have availed myself of the thoroughly practical suggestions contained in the leader on the "Elimination of Silver from the Whites of Albuminized Paper Prints" (page 61), and with considerable advantage. In my original formula I used two drachms of sulphate of ammonia and three ounces of hyposulphite of soda. The paper above referred to says, use an ounce of the ammonia salt. Now, my idea was, that the hyposulphite of soda would do almost all the fixing, and that its action only wanted to be very slightly supplemented by a little of the hyposulphite of ammonia to render its action quite perfect; and therefore I suggested adding only so small a portion of the sulphate of ammonia as two drachms. I have, however, tried the larger, or, at least, a larger, portion of this salt, and find from it great advantage.

Having tried this, to satisfy myself as to the practical working of the bath I made up the following, using up in it the old bath mentioned in the News of February 7th, and which had been made up some days previously:—

Water	...	...	...	16 ounces
Hyposulphite of soda	...	...	6	"
Sulphate of ammonia	...	about	1 ounce	
Acetate of soda	...	...	2 drachms	
Gold	...	...	10 or 12 grains.	

The gold which I use is only very slightly acid, if at all. To correct any acidity, however, which it might convey to the bath, I added just a trace of ammonia to the solution before putting in the gold (somewhere about one-third of a drop). If the gold were very acid, no doubt the safer plan would be to neutralize it separately.

This bath has remained in occasional use ever since, and is now, to all appearance, in as good working order as it was at first. I have made up waste from time to time with

a little fresh solution of hyposulphite of soda, and each time of using it I have added just a little gold, to prevent it from "jibbing," as Mr. Hughes says. I have treated the solution with no particular care, always leaving it in the dish in the dark room. At first I left it uncovered, as recommended by Prof. Towler, but finding dust, &c., accumulate, I filtered it, and have since kept it covered up with a glass plate when not in use.

I am sorry that I have no record of the number of prints which have been fixed in the bath, but there have been a considerable number from first to last. The only apparent effect produced in the solution is a very slight discolouration and a little sediment; this latter I attribute entirely to the chloride of silver being precipitated by the impurities of the water, as I have, of course, used only common water in these experiments. This precipitate, when the bath is used, becomes stirred up, and renders the solution milky, but does no further harm. I have not, in any instance, washed the prints before immersing them in the solution. In some instances I have toned prints four days after printing (two of the horses sent are done so, and the other printed and toned the same day), and I have found no difference in the result. Any kind of paper seems to tone well (I mean any good paper), and the results are equally good with a 60-grain bath or with a 20-grain and gelatine, as recommended some time ago by Mr. Palmer.

Your readers will now be anxious to know what are the fixing powers of the bath after being so used. I will proceed to describe the treatment of the two half stereo prints which have been tested for silver in the whites.

Messrs. Mawson and Swan, with a courtesy which I have always received from them, had no sooner read my last paper in the News than they sent me a letter stating that, to aid in my experiments, they had forwarded me some hyposulphite of ammonia, in order that I might try its effects. The next day the salt came in a railway parcel, done up in several sheets of paper. The appearance of the stuff is that of the soda salt, and it has about the same moisture; it has been kept ever since in a stone jar, with a loose cover, without getting any more moist. Just as I was about to use this sample for some experiment, a letter came again from Messrs. Mawson and Swan, stating that, by accident, an impure sample had been sent me, at the same time asking me to put it on one side and wait a day or two for a fresh supply. Of course, under these circumstances, I did not use any of the impure salt to form a toning bath; but I have used a solution of it, one ounce to about eight of water, as a *refixing* solution for the prints after they came from the bath above mentioned. The last batch of prints from the toning bath were passed through this refixing solution, each print remaining in it about three minutes.

The two half stereo prints (enclosed) are typical examples of the result produced: the one of a dark tone having been a full time in toning bath, and so exposed, of course, to its most perfect fixing action; and the other, of a browner colour, which was produced in a comparatively short time in the toning bath. Both these were treated, after the extra fixing mentioned, with a solution of hydrosulphate of ammonia one drachm, water one ounce. The dark one enjoyed the influence of this solution for fifteen minutes, the light one for ten minutes. It will be seen that, though the *half-tones* have been turned very yellow by this solution, the whites are very little stained by it; certainly much less so than those I formerly sent, and very much less than would be the case with prints fixed only in the soda\* salt in the usual way. The general quality of the toning may be judged of by the few samples enclosed.

I think, from what I have stated, we may conclude that the

\* It should here be stated that this experiment illustrates that the use of a second fresh bath of hyposulphite of soda is valuable in diminishing the amount of silver left in the whites, the imperfection in the sample of hyposulphite of ammonia consisting in the fact that it contained a large proportion of hyposulphite of soda, as we ascertained from the examination of a sample sent to us at the same time.—Ed.

toning and fixing bath made up as recommended is certainly a solution which deserves further investigation; its results are certain, its manipulation easy, the tones it gives are good, the time it takes to produce them is not excessive, and, finally, the fixation, aided by a short immersion in hyposulphite of ammonia (a confessedly imperfect sample, too), is perfect; for I think if priuils will stand the test to which these have been submitted there is not much fear of their fading from silver left in the whites; that is, from imperfect fixation.

I hope to investigate the matter more fully anon, and look forward with much pleasure to the receipt of the *pure* sample of hyposulphite of ammonia promised from Newcastle, as I cannot but think it will prove even more efficient than the mixed salt hitherto recommended. It does not seem to me there will be any difficulty in getting this ammonia salt when wanted, as another chemist, of high repute among photographers, says, in a letter received a few days back: "I shall be happy to supply as much hyposulphite of ammonia as photographers call for."

I hope that those photographers who take an interest in these experiments will make some trials for themselves, as it would be useful and good in all ways to have the results I have described confirmed by independent testimony; and should any discrepancies arise, the discussion of them could not fail to elucidate some point of interest connected with the matter, and might add greatly to the usefulness of these remarks.

## THE MAGIC LANTERN AND PHOTOGRAPHY.

BY JAMES MARTIN.

No. 8.

SINCERELY hoping that the instructions given in the foregoing papers will enable those of my readers who persevere to paint and mount in its holder the photographic transparency or outline with success, I now proceed, according to promise, to describe the various sorts of lanterns, their appliances, how to light, and how to use them.

Lanterns are made of various sizes, governed by the size of the lenses to be used; therefore, before commencing to make one, that question must be decided, as it will not only govern the size of the lantern, but its cost, its portability, and its general utility. The most useful sizes are those having the condensers of from 3 to 4 inches in diameter. A smaller-sized picture than 3 inches in diameter will contain very little subject-matter. When the condensers are above 4 inches in diameter, the expense of everything belonging to the apparatus is enormously increased, it becomes very cumbersome, and only fit for a large hall or public lecture-room. As 3½-inch pictures are almost universally sold, and to this sized lantern the quarter-plate lens can be fitted as objective, I will give the details and mode of construction of a suitable lantern.

The bodies of lanterns are usually made of japanned tin, sheet iron, zinc, or other suitable metal; they are also made of wood lined with metal. The top and chimney should, in all cases, be made of metal only; and the joints seamed, not soldered, as the great heat might cause the solder to run. When the body is made of wood, the parts should be screwed together like a well-made camera. The dimensions of the body of a lantern for lenses of the size recommended are as follows:—Height, 15 inches; length, 8½ inches; breadth, 6 inches; height of the chimney, 13 inches; diameter at the base, 4½ inches, tapering to 2½ inches at the upper small end, where it must have a crook or bend, to prevent the light from showing into the room. I prefer having a door at the back and side, and this plan will be found most convenient. The door may be about 4 inches wide, and must be of sufficient height to allow of the lighted lamp, with its glass chimney fixed, being placed on the lamp-stage while being held upright. There must be a stout wire handle affixed to the upper part of each of the two sides. The door is placed on the right-hand side, except when

lanterns are made to be used in pairs; in that case the doors are one on the right-hand side of one lantern, the other on the left-hand side of its fellow. A circular orifice is made on the top, round which a collar is fixed of about three-quarters of an inch in depth, in which the chimney fits. In the front a round orifice is made of 3½ inches in diameter, and its height from the base must be governed by the height of the lamp or other means of lighting to be used, and so arranged that the centre of the flame shall be opposite the centre of the orifice. The nozzle of the lantern consists of a cone with an aperture corresponding with that cut in the front of the body, and placed at its larger end upon a metal plate, to be fixed at a distance of one inch from the lantern, having inside this plate another which is allowed to play freely in front of the body by two springs. The slide is placed between the loose plate and the body. The nozzle may be made to slip on and off the front of the body; this method will be found very convenient for packing, as when two lanterns are used the chimneys and lamps can be packed in one, and the nozzles with their lenses in the other, and the whole contained in a square box of comparatively small dimensions. In front of the cone there are two tubes fitted, one within the other, so that the inner one slides easily in and out in the outer one; and at the back are placed the focussing lenses when it is intended that a portrait combination shall be used. I should recommend that either the cone should be turned of wood, or have a wooden face at its smaller end, so that the flange of the lens may be screwed to it. This method will prevent any necessity of trusting (perhaps) a valuable lens in the hands of an unskilled workman, a proceeding most certainly to be avoided. Inside the lantern, close and opposite to the opening cut in the front, must be placed the condenser, fitted in a bolter or flange as may be. About one inch from the bottom is placed the lamp-stage, having a sliding arrangement to regulate the distance of the lamp from the condenser, and moved to and fro by means of a wire handle passing through the back of the lantern. A small circular rim is made in the centre of the stage, in which the lamp is placed; and in the centre of this rim a hole is cut to enable air to pass up the tube of the lamp. Holes are also cut round the sides for the purpose of ventilation. The lamp-stage can be so arranged that it can be removed altogether, and the hydro-oxygen light used when required.

The efficiency of the lantern depends in the greatest degree upon the quality, position, and suitability of the lenses employed. If they are not of the proper description and focus, and placed at the right distance from the light and from each other, no satisfactory result will be obtained. The use of the largest lens is to concentrate or condense the rays of light from its source upon the focussing lenses, and, by thus bringing them into proper relations, increasing the brilliancy of the picture thrown on the screen. This lens is called the condenser. The glass used for the condensers should be of the very best quality, free from specks, bubbles, and striae, especially when a strong light is used, as every imperfection is then shown and enormously exaggerated. A plano-convex or a meniscus lens may be used of about five inches focus, but the compound condenser, consisting of two lenses so curved as to give a brighter and flatter field, is far preferable, although more costly. The front or focussing may be either a quarter-plate portrait lens or a plano-convex lens of about four inches focus; or, still better, a pair of them, having the same equivalent focus.

The best form of lamp is the cup lamp, on the Argand principle; and the best oil, pure sperm, with gum camphor added as before advised. The best Florence oil is also very good for the purpose, adding the camphor as before.

Let me here seriously caution my readers not to use any explosive or mineral oil in paraffine or other lamps inside the lantern, as, from the great heat engendered, there is imminent danger of explosion. Common coal gas is all but useless, as it affords much less light than a good oil lamp.

114, High Street, Ilfracombe, Devon.

### LAST WORDS OF SIR D. BREWSTER ON PHOTOGRAPHY.

THE following are the remarks written by the late Sir David Brewster, as a part of the address intended to have been delivered before the Edinburgh Royal Society, had illness not prevented:—

In most of our provincial towns there is a museum of natural history and antiquities, which would be a valuable auxiliary in teaching natural science in the neighbouring school. But even where no such collection exists, a small museum might be established in the humblest of our schools. Within their own narrow sphere objects of natural history might be obtained, and many a private collection in the district would surrender a tithe of its specimens for public use. Our Industrial Museum, too, might distribute a portion of its overflowing collections; and even the British Museum might contribute some of its innumerable duplicates, and bring into use its accumulated and unproductive treasures. Itinerant museums, like the itinerant libraries, might be chartered in the same cause, and might sell or exchange the duplicates which are found in different localities. By these means our school museums might obtain specimens of the more important rocks which form the carpentry of our globe, of the metallic ores, and the metals themselves which are in daily use, of the more precious minerals which are employed for the purposes of art or ornament, and thus give to the youthful student some knowledge of the world on which he resides, and of the elements of civilization which it embodies. In the departments of Zoology and Botany we cannot expect to collect specimens for our schools; but our travelling menageries and the museums and botanic gardens of our principal towns would supply, to a great extent, the means of instruction.

But even when these are beyond our reach, photography, and the stereoscope, which gives relief to its pictures, might be advantageously employed. The photographic process will give us accurate representations of those objects, both of nature and of art, which it would be desirable to describe and to explain in the instruction of youth. In the department of Zoology the picture might be often taken from the living animal, standing before the camera in vigorous life and transcendent beauty; or, when this cannot be done, from the fine specimens of zoological forms which adorn our metropolitan and provincial museums. With equal accuracy might be represented the osteology and integuments of animals, the framework which protects life, and to which life gives activity and power. The trees and plants, too, of distant zones will show themselves in true relief—the Banyan clinging with its hundred roots to the ground; the Bread-fruit tree, with its beneficent burden; or the deadly Upas, preparing its poison for the arrow of the savage or the point of the assassin. With no less interest will the school-boy gaze on the structures of the inorganic world—the minerals which have lain in the earth beneath his feet, the crystals which chemistry has conjured into being, displaying to him their geometric forms, infinite in variety, and interesting from their rarity and value. Painted by the very light which they reflect, he will see the Koh-i-noor and other diamonds, and the huge rubies and sapphires and emeralds which have adorned the chaplet of beauty and sparkled in the diadems of kings. The gigantic productions of the earth will appeal to him with equal power—the colossal granites which have travelled in chariots of ice, the precipices of ancient lava, the Doric colonnades of basalt, and the fossil giants of the primeval world, which trod the earth during its preparation for man, and have been embalmed in stone to instruct and to humble him. In acquiring a knowledge of physical geography, of the grander aspects of nature, their representations in relief will be peculiarly instructive. The mountain range, whether scarred with peaks or undulating in outline; the volcano ejecting its burning missiles; the fixed or the floating iceberg; the glacier and its moraines; and even the colossal wave, with its foaming crest, will be portrayed in all the grandeur of nature. The works of human hands, too, will stand before the scholar in their pristine solidity or their ruined grandeur; the monuments by which sovereigns and nations perpetuate their names; the pyramids (with their mysterious legacy to science), the gorgeous palaces of kings, the garish temples of superstition, and the bastions and strongholds of war will be seen as if the observer were placed at their base and warmed by the very sun which shines upon their walls. Although few of our village youth may

become sculptors, yet the sight of ancient statues, in actual relief, and in their real apparent magnitude, cannot fail to instruct and to refine them. To gaze upon the masterpieces of ancient art, standing in the very halls which they occupy, or to contemplate the *chefs-d'œuvre* of modern or living artists, with the sculptor himself standing by their side, must excite an interest of no ordinary kind. The works of the architect, the engineer, and the mechanist may also be exhibited in full relief at our schools—the gigantic aqueducts of ancient and modern times; the viaducts and bridges which span our valleys and our rivers; and the living machinery in our factories and workshops, which toil daily for our benefit, and supply the commerce of the world. With such means in our power, cheaply obtained and easily supplied, a large portion of scientific instruction may be instilled into the youth of our schools, familiarizing them with the works of their Maker, and preparing them for the reception of that higher revelation with which these truths of science cannot fail to harmonize.

### FURTHER REMARKS UPON THE USE OF PERMANGANATE OF POTASH.

BY J. R. JOHNSON.

[The following is the communication forwarded to the last meeting of the Photographic Society by Mr. Johnson.]

Since I had the honour of calling attention to this subject at the last meeting of the Society, I have had further experience of the use of the permanganate, and have elicited some facts which are worthy of note, and which I will describe. Before doing so, however, I will make a few remarks with the view of removing some misapprehension as to the nature of the salt used.

It is not Condyl's fluid of which I recommend the use, but pure permanganate of potash, which may be obtained from any dealer in pure chemicals, in the state of definite-shaped crystals and of nearly absolute purity. These dissolve readily in about sixteen times their weight of water, forming a rich violet solution. A solution of about ten grains to the ounce will be found of convenient strength. On dropping this solution into the bath, the latter assumes a brilliant reddish-purple hue, which is due to the formation of permanganate of silver, if the bath be neutral; or to permanganic acid, if the bath be acidulated with nitric acid. Both these substances appear to act with equal power; but I strongly recommend that the acid be first neutralized, as there is then little doubt that the manganese from the deoxidized permanganate will be precipitated as the peroxide; whereas if nitric acid be present, a portion of this may be taken up in the presence of organic matter to form nitrate of manganese.

Only a small quantity of the permanganate solution should be added at one time. If it be added in too large a proportion, the permanganate of silver (which is sparingly soluble, requiring 109 times its weight of water for solution) is precipitated, and not only reduces the strength of the silver bath, but becomes useless, being carried out of the range of the substance to be oxidized. The colour which the bath first assumes changes gradually to a brownish olive hue, while the bath becomes turbid from the precipitated oxides. A further small quantity should then be added, and the reaction again watched, until completed. By this means the whole of the noxious ingredient, whatever it may prove to be, is removed, and the bath is made to work as clearly as before.

Care should be taken to leave no excess of the permanganate in the bath, as I find that it acts as a most powerful retarder or destroyer of the latent image, even when in small quantity. I believe that the same may also be said, to some extent, of the nitrate of manganese, for an acid bath appears to work more slowly after being acted upon by the permanganate, even when no excess of this salt has been left in the bath.

Fortunately we possess a very ready mode of eliminating all excess of permanganate, even if it should exist in considerable quantity. All that is necessary is to pass a solu-

tion containing it once or twice through a paper filter, when every trace of the salt is removed by the action of the cellulose of the paper reducing the permanganate. As the colour is a sufficient test of the presence of the salt, no difficulty exists in this respect. But for this facile method of separating the permanganate and detecting its presence, the process would be impracticable, as the retarding action of the permanganate is most energetic.

## PHOTOGRAPHIC DIFFICULTIES OF AN AMATEUR IN SOUTH AFRICA.

BY DR. MANN.\*

THE act to which I stand committed to-night, of appearing before the Photographic Society of London with an "Amateur's Difficulties," is a bold one, and stands in need of some apology. Indeed, I may as well make a clean breast of it from the beginning, and confess that the proceeding itself is the last and largest "difficulty" in my budget. It is only after some delay and consideration that I have ventured upon the course. I have but little to tell, and still less to show. But, on the other hand, I have much to ask. It is matter of familiar and general knowledge that the grandest and highest branches of human science are also the most liberal and cosmopolitan. The photographic societies of the world have done much to find for the pursuit that engages their attention a forward position among these high and liberal branches of human knowledge. It is not for me, in this presence, to say that the Photographic Society of London is in this particular not one whit behind the very best of its colleagues; but it is for me, in this presence, to say that I have designedly and discreetly put faith in this fact, and drawn upon the indulgence of an association devoted to the advancement of a liberal art, in laying aside my repugnance to appear with my small amateur dish at so distinguished and well-appointed a board.

In further deprecation of my proceeding, I should, perhaps, also add that, to my own mind, it seems well worthy of consideration that in the now somewhat large class of survivors who carry small dishes—namely, that of the so-called "amateurs" of scientific pursuits—there are many who are circumstanced like myself; that is to say, who have a deep and intelligent interest in the principles and progress of some branch of knowledge and art which has raised and compacted itself into a definite practice and profession, but who, on account of the exigencies and strain of other important demands upon their time, can only meddle with such matters at fitful, brief, and uncertain intervals, but who, nevertheless, can incidentally turn such an art as photography to most excellent account in carrying out investigations in other important fields. I have myself pretty well followed all that has been done in photography, as I have followed what has been done in physiology, in astronomy, and in other branches of research, on account of the intrinsic interest there necessarily is for the informed and intelligent mind in the knowledge itself. But I have practically dabbled with the processes of the art; I have qualified to carry my small dish, and write myself down "amateur," because I have desired at the least possible expenditure of time to be able to secure certain enduring records, notes, and suggestions of matters and objects that have come under investigation in a somewhat out-of-the-way field of research. Now, on looking back upon my labours and doings in this particular, I am of necessity painfully conscious that I have lost many records that I should have been but too glad to secure; and that I have wasted many valuable hours that I should certainly have turned to account, if I could have had either my present experience or better guidance at my start among the difficulties that I have to speak of. I am quite aware that there are amateurs who can and do achieve excellent results and marked success, even among such obstacles as I have had to flounder amidst. But I need not say such amateurs are of the "cream scientific of the earth." It is not for such men that the light of experience and the fetters of technical instruction are required; they move under the inherent force of the inspiration and fire that is within them. The light of experience and the fetters of instruction are required to enable less gifted and more ordinary mortals to accomplish useful, satisfactory, and steady work. I think it is now quite possible to apply the suggestion contained in these remarks to the marking out of a photographic process which shall be at

once convenient, handy, and sure for ordinary scientific travellers in remote countries and hot climates; and I fancy that my own experience has given me some inkling of the instrumentality by which this may be done. If ever again I return to the field where my own work has chiefly lain during the past ten years, I shall hope to do so in the possession of some such advantage. I am quite sure I shall be more likely to do so if I succeed in getting the members of the Photographic Society of London to realize what the precise difficulties are with which their amateur brethren have to contend in circumstances such as I am about to describe, and to consider the suggestions which I purpose to submit. Here, then, is the second argument which has contributed to bring me into the predicament in which I stand.

A third influence has also operated in over-ruling the natural instincts of my diffidence and modesty; and I am sure you will forgive me if I let you into the secret of this. Having recently returned to England, to which I am bound by very strong scientific and social sympathies, after an absence of some years, I am personally very glad indeed to avail myself of this pleasant opportunity and excuse to scrape an acquaintance with men so deserving of esteem as the photographers of England.

To pass on from apology to matter of fact: the great cause which underlies the difficulties the photographer has to deal with in Natal, the South-African land where my own experiences have been gleaned, is that it is a nearly tropical land, where molecular and chemical change are energetic and quick, and where actinism is capricious and slow. But this is not all. The season of summer, when the natural temperature is at the highest, is a season of frequent rain and superabundant moisture, when the air very closely resembles that of the hot-house conservatories at Kew; but when, also, as if that were not a sufficient photographic embarrassment, there occur at frequent intervals dry land-winds or siroccos that shrivel the leaves of trees and shrubs, and that crack the substance of wooden furniture by their parching touch. In the winter season, which is a period of moderate temperature and of almost unbroken sunshine, and when the perplexed photographer rejoices in the opportunity of getting out of the "frying-pan," he is unfortunately almost sure to find that he has only jumped "out of the frying-pan into the fire;" for at that season, when South-African nature has got rid of her superabundant dripping moisture, she perversely, and, I must add, most unfairly and inconsiderately, extemporizes a long period of "yellow calico." Throughout the dry winter the face of the country is more or less continuously covered with burning grass, and the sky is encumbered with a clinging and almost permanent veil of saffron smoke, which at times makes the photographer sigh for the chance of again getting back from the fire into his "frying-pan"—a "prison-house" photographical, whose "secrets" I now proceed to reveal.

There is one very important condition that underlies all "frying-pans," namely that of temperature, which now, in the first place, claims a few pointed words. The mean temperature of the year in Natal, at the height of 2,000 feet above the sea, is 64.7 degrees. On the coast the mean temperature of the year is a trifle above 69 degrees. The mean temperature of the six months of summer is 69 degrees, and the mean temperature of the six months of winter 60 degrees. The mean temperature of the several months varies from 55.2 degrees to 71.8 degrees. In winter the temperature of the day ordinarily rises above 70 degrees. In summer it commonly rises somewhere between 80 degrees and 86 degrees, and, when the dry land-wind is blowing, to somewhere between 86 degrees and 97 degrees. But high temperatures occur at all periods of the year. Thus, during a period of eight years I have recorded the temperatures of the air in the shade, hereafter named in each of the specified months of the year, namely:—

January	...	...	...	...	...	93.0
February	...	...	...	...	...	97.1
March	...	...	...	...	...	92.8
April	...	...	...	...	...	89.5
May	...	...	...	...	...	85.2
June	...	...	...	...	...	78.2
July	...	...	...	...	...	82.2
August	...	...	...	...	...	89.8
September	...	...	...	...	...	95.4
October	...	...	...	...	...	96.0
November	...	...	...	...	...	97.2
December	...	...	...	...	...	97.6

\* Read before the London Photographic Society, March 10th, 1868.

I fear that very few of my present audience can altogether realize the pleasure of laying a collodion film in a tent under a blazing sunshine at these temperatures, as I have done, especially when the only sample at command has been a cadmium one, with an African ticket of naturalization of some twelve months' date.

Collodion is naturally the first substantive topic that rises to the surface as I proceed to tell my tale; and I think, in regard to it, I may at once and roundly state that the collodion, on the whole, I met the least trouble with, was the simply-iodized samples prepared by Mr. Thomas, of nine or ten years ago, which used to cover the glass with a thick yellow creamy film. I rarely had any other trouble with those samples than their getting slow of action after long keeping. They certainly were easier to work with—both on the ground of cleanness and of mechanical firmness—than any other kind that I have used. I was rarely troubled with stains of development with them in the most unmanageable temperatures, and I was never annoyed with the splitting and separation of films. After the introduction of the improvements in the manufacture of some eight years ago this was altogether changed. Every sample of collodion that then came to me was affected by the same perverse idiosyncrasy of being extremely difficult to lay after the bottle had been opened for a few hours, or perhaps days. In anything above the lowest temperatures it gelatinized in ridges before it could be got off the plate, even with the quickest handling; and this, as a rule, I found the radical defect of all the cadmium collodions in South African conditions and circumstances. I was at one time exceedingly delighted with some thin collodion of Mr. Hockiu's that I lit upon accidentally. It worked with great ease and pleasantness, and gave me plates with deep shadows and abundance of half-tone. But in every case this collodion covered itself with close reticulations after drying. Three, if not four, different tubes all gave the same result, both in my own hands and in those of a really able friend, acting independently. I have not a single plate left of many which were made with these collodions; the separation of collodion films from the glass, upon re-wetting for after-intensification or handling, is of very common occurrence. This, no doubt, is due to the positive impossibility of having the glass actually dry when the film is laid in the warm, almost saturated, atmospheres that have to be dealt with. Vapour is again settling on the glass the instant it is removed. Another very unpleasant form in which this influence, and probably in connection with it the inequality of drying (almost sure to be encountered under the circumstances) operates, is the sudden explosion of the film, some time after its complete drying, into a myriad of fragments. Some hours after the plate has been put by and considered all safe, cracks, like the fissures of starred glass, suddenly radiate in all directions, with a mischievous rustle. Of a very considerable number of studies of Katfir domestic architecture that I made upon one occasion, and that I valued for a special reason, all my best specimens have been destroyed from this cause.

I have no doubt whatever that long keeping of collodion in temperatures such as have to be braved in Natal does not answer. The mechanical texture of the collodion undergoes deterioration; and no amount of dilution with ether and alcohol to keep down the thickness of the liquid to convenient working density, can be relied upon on this account. In my own practice I always found the mechanical imperfections exasperated by extemporaneous additions of the solvent.

Here, then, comes the first point to which I desire to draw attention, and upon which I wish to seek counsel. I incline to think that the most satisfactory course that the amateur could adopt, in such external conditions as obtain in countries like Natal, would be to keep the pyroxyline in a dry state, and to have a good supply of the proper solvents constantly in store in small, well-closed receptacles, and so always to prepare just what collodion is likely to be required for each occasion some fourteen or twenty days before it is to be used. It would possibly be still better to prepare the pyroxyline itself from time to time; but this the amateur, who is otherwise pressed with occupation, will never do. It may be perhaps necessary that I should here again remark that it is solely from the amateur point of view that I am bringing forward my plea. I am speaking of men who, after weeks, or perhaps months, of forced abstinence from photographic pursuits, suddenly find some stray days, or some chance opportunity, when they can turn the art to account, and reap passing pleasure in its practice, if they have only the means at hand of doing so with fair certainty of working with-

out too great consumption of time, and with at least average success. The professional photographer can always arrange to have his collodions arriving from England at convenient intervals, and in a constant stream.

The nitrate of silver bath is far less troublesome in sub-tropical climates than the collodion; it is easily kept in fair working order; but there is one point in regard to it that may be worth a passing mention. My own practice was almost invariably to neutralize with freshly prepared oxide of silver, and then add as little nitric acid as I could work with. But I had a friend and companion in arms in Natal, who was naturally an exceedingly good manipulator, who used literally, when out on an excursion in the hot season, to pour nitric acid into his bath in an unmeasured stream, and who used continually to get good results in this way, whilst I was still floundering in streak and fog. My friend was originally my own pupil in the art, but he passed by his master at a very early period of the pleasant connection. From my own inability to get myself boldly and freely out of my earlier convictions and beliefs, I could never quite bring myself to follow the bold lead of my companion. But in illustration of the results of his heroic practice, I am able to submit to the Society some failures of my own by the side of successes of my friend, both produced at the same time and by the same materials, and in the presence of very unfavourable conditions of temperature—the only difference in the two cases being that I was painfully and obstinately trying to feel my way out of neutrality by the most cautious advance, while he was simply revelling in a nitric acid sea of unknown and unguessed depth. I am also able to submit at least one specimen of an instantaneous photograph made by this bold practice under the hot sunshine. In this illustration the curl of the breaking sea is clearly rendered.

(To be continued.)

## Proceedings of Societies.

### SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE usual Monthly Meeting of this Society was held in the City of London College on the evening of Thursday, March 12th, the Rev. F. F. STATHAM, M.A., F.G.S., in the chair.

The minutes of a previous meeting were read and confirmed.

No paper having been provided for the evening, the Question Box was examined, and of several questions introduced which had received the sanction of the Committee, one referring to the use of permanganate of potash for rectifying disordered nitrate baths was selected for consideration, and was, on the invitation of the Chairman, opened by

Mr. JOHNSON, who briefly related his experiences as already described in our columns. In his more recent experiences he had found it desirable that the bath should be neutralized before adding the permanganate. Care should also be taken not to have excess, for he found that permanganate present in the bath tended to retard the formation of the image, and so destroyed sensitiveness. He had also found that a 10-grain solution, as recommended by Mr. Simpson, was strong enough. The colour was an excellent test as to the proper quantity: if it were added a little at a time until the faintest trace of a pink tint remained in the bath, the effect would be produced, and this trace would be removed by contact with the organic matter furnished by the filtering-paper in the course of one or two filtrations. In reply to some questions, he said that the accumulations in old baths which caused fog were undoubtedly of an organic character. The alcohol and ether becoming oxidized by the iodine, nitric acid, &c., doubtless formed, as Mr. Simpson had suggested, aldehyde, which, having a reducing tendency, caused fog; and this body was removed by the action of the permanganate.

After some conversation, in which the Chairman, Mr. Pierco, Mr. Johnson, and others, took part,

Mr. WHARTON SIMPSON detailed the results of some experiments with the permanganate of potash (see p. 122 in our last).

In reply to some further questions, Mr. JOHNSON said that when the bath at once became brown and turbid without passing through the pink stage, it was clear that too much of the permanganate had been added. He thought that Condy's fluid should not be used, as it was often impure. If the permanganate

ate were added a little at a time, the whole of the alcohol and ether would be oxidized before any excess of permanganate would remain.

Mr. SIMPSON said it would be scarcely desirable to proceed to that point, inasmuch as alcohol and ether in their normal condition would not exercise any injurious effect, and their perfect oxidation would cause an accumulation of carbonate and acetate of potash in the bath. As it fortunately happened that the aldehyde formed by the decomposition of the alcohol, &c., which was the source of fogging, was acted upon and removed first by the permanganate, there was no need to add excess, which would tend to waste silver and injure sensitiveness. Any body which readily gave up oxygen would necessarily retard the formation and the development of the images.

Mr. SEBASTIAN DAVIS, after referring to the old method of testing water for organic matter, in which, after evaporation, the residue was burnt to ascertain the proportion of organic matter present, and pointing out the superiority of the present method, remarked that in order to examine the colour more perfectly it was customary to place the water to be tested in a tube two or three feet in length, in which the colour could be readily seen. He agreed with Mr. Simpson as to the retarding action of a permanganate, as it was a salt containing seven equivalents of oxygen, which it readily gave up; and the presence of such a salt during development, by peroxidizing the iron, would materially check its reducing action.

Mr. HART suggested, in order to avoid the risk of adding excess of permanganate, that a small portion of the bath might be taken, and, after precipitating the silver with a chloride, the permanganate might be added to the water cautiously until all organic matter was removed. By this means an estimate of the quantity required for the whole bath might be formed. He would like to know if Mr. Johnson had examined the precipitate to ascertain if nothing but sesquioxide of manganese was thrown down.

Mr. JOHNSON said the quantity of precipitate was so small that he had not attempted such an examination. He thought, however, that the reactions had been so fully stated by Mr. Crookes in the NEWS, that no doubt need be entertained on the subject.

After some desultory conversation, in which Mr. Hart suggested the importance of photographers publishing a record of their results with this remedy, and stated his thought that a portion of the silver would be thrown down as well as oxide of manganese,

Mr. SIMPSON stated that he believed not until excess had been added. The precipitate thrown down in the first case he had described, in which he used care to avoid excess, was of a different character to that thrown down when excess was added. The first was of a cold brown tint, the second of a purple brown tint, and, when examined, was found to contain permanganate of silver.

Mr. JOHNSON said that there could be little doubt that the safest and most efficient plan would be to use permanganate of silver, as suggested by Mr. Crookes.

Mr. BLANCHARD said that he had used Condé's fluid in one case to a bath, and had doubtless, although he used very little, added more than was necessary. A plate he tried was free from fog, but it was covered with fine needle-shaped crystals. On diluting and filtering, all this was removed, but still the bath worked a little slower.

Mr. JOHNSON again said that he thought it unwise to use Condé's fluid.

After some further conversation,

Mr. FOXLEE said that he had never had any difficulty in getting cleanness with doctored baths, but they never gave him so much sensitiveness as an undoctored bath.

Mr. SIMPSON said that in the bath he had tried the sensitiveness was greater after treatment than before. He believed that Mr. Blanchard had repeatedly found a corrected bath gave quicker results, as well as better, than he could obtain from an uncorrected bath.

Mr. BLANCHARD said that he often found that a bath treated with carbonate of soda and sunned gave him the highest sensitiveness and the highest quality.

Mr. FITCH confirmed this view.

Mr. FOXLEE said that his corrected baths were not slower than before correction, but slower than the new bath made with the purest fused nitrate of silver in the market.

After some further conversation, Mr. FOXLEE described a bath which sunning failed to improve, its fault being a ten-

dency to turning red in the shadows during intensifying. It was suggested that this defect would furnish matter for an evening's discussion.

The subject was then closed with a vote of thanks to Mr. Johnson.

The SECRETARY exhibited an old developed Talbotype, of which scarcely any trace was left. The print was cut up and divided amongst several members for experiments in revival.

Mr. SIMPSON exhibited a carbon print, produced in Berlin, by Swan's process, which appeared as the frontispiece to a German translation of his (Mr. Simpson's) work on Photography in Pigments.

The proceedings then terminated.

The next meeting, in April, will be devoted to examination and conversation upon photographs, which members are requested to bring for the purpose.

## Correspondence.

### PHOTOGRAPHY AND DISEASE.

SIR,—I think the question now being discussed in your columns, as to whether the practice of photography is unhealthy or not, must in a great degree be settled by the testimony of experience.

After sixteen years' handling and inhaling the deadly agents we use, I have had no symptoms of suffering from poison, and I am convinced that if the dictates of common sense were followed, no danger need be apprehended from their use; but if discretion is not used, we know that a man may lose his life by eating roast-beef and plum pudding. If prudence is necessary in the one case, it is surely doubly so in the other; otherwise the consequences will be the same.

During this period of my practice I do not pretend to say that I have not many a time been ailing with headache, and, I am not ashamed to say, "heartache" also. What with the overlearning which the progress of the art has rendered necessary, and the hard struggle to keep the "cart on the wheels" through the withering blast of unscrupulous competition, I have often wondered at my own endurance. I am sure, sir, that you will agree with me when I say that I feel it no small mercy to have come thus far out of the battle with unimpaired health and a comfortable prospect.

I have watched the course of many who prefer "gold to honour;" some have gained the prize; others, in their haste to be rich, have fallen, to rise no more. This hit-or-miss policy has of late come sadly to grief, for the good and honest reason that it has out-generalled itself; but for photographers proper there never has been a brighter prospect. Those who have striven to do their best for the art and their patrons have gained a position which is as essential in the science of trade as it is in the science of war.

Photography must always be a worrying and trying profession, but I believe that the worst is past, and that health and wealth are in store for the future.

W. HALL.

Brighton, March 17th, 1868.

### THE USE OF DISTILLED WATER.

SIR,—The important question recently raised in your columns by Mr. Cherrill, as to the necessity of using distilled water in photography, although ably discussed by some of your correspondents as well as by the gentleman raising the question, has scarcely, I think, been set at rest. Mr. Cherrill himself tells us that he dispenses with distilled water; Mr. Russell Sedgwick, an old and experienced photographer, makes a similar statement. Statements of practice are always of considerable importance; but I should like to know the reason why of two or three points. In the first place, what constitutes "common water"? In the next place, presuming it to be, as I fancy it is, the ordinary water used for domestic purposes, does not this vary considerably in quality, according to the source from whence it is derived? And do not many samples contain chlorides, carbonates, sulphates, &c., as well as organic matter? If this be so, do we not run considerable risk of introducing contaminations into a new silver bath, which may subsequently cost us much trouble to get rid of?

I am a great advocate for simplicity wherever it can be obtained without paying too great a price. Will you enlighten

me on the subjects I have named, and also say what is the effect in a nitrate bath of having the impurities common in such a water as that of the New River Company?—Very respectfully yours,  
AQUARIUS.

### BLISTERS IN ALBUMINIZED PAPER.

DEAR SIR,—It is with much pleasure I read Mr. Bovey's paper on the all-important subject of photographic printing, and I am glad to find that he, by the opinions he has expressed, has confirmed mine, viz., that the cause of blistering of albuminized prints is most reasonably accounted for by imperfect coagulation of the albumen.

With thanks to Mr. Bovey and the journal in which he writes,—I am, yours &c.,  
VESICULA.

March 14th, 1868.

### Talk in the Studio.

INTERNATIONAL COPYRIGHT WITH AMERICA.—An International Copyright Bill has been laid before the American Parliament. It is to be hoped that it will include works of fine art as well as literature, in which case the provisions of the Fine Art Copyright Act of 1868, in which photographs are protected, may probably be comprehended in the new law.

THE CHEMICAL SOCIETY'S SOIREE.—On Wednesday evening, 11th inst., the President and Mrs. Warren De la Rue held a reception at Willis's Rooms, St. James's, which, notwithstanding the unfavourable state of the weather, was attended by a numerous and distinguished assembly, both of members and visitors, including many ladies. The exhibition of objects was varied and interesting. Many gems of art were displayed, in the shape of paintings by Guido, Gainsborough, and Turner; sculpture, Japanese porcelain, ivory carvings, and other articles of *vertu*. There were likewise a goodly selection of etchings by Hanhart, photographs and photo-lithographs from the Royal Arsenal at Woolwich, and others, illustrative of special novelties in the way of mechanical construction. A splendid series of new photo-enamel portraits was exhibited by M. F. Joubert. The phosphorescent figures of M. Gaiiffe—the butterflies, &c., lately described in this Journal—were exhibited by Messrs. Murray and Heath, who sent, also, some exquisite examples of stereo-photography. Mr. Thomas displayed his field tent in working order, and some beautiful samples of nitrate of silver, iodide of cadmium, and other photographic chemicals. Messrs. Hopkin and Williams showed specimens of alkaloids, a large bar of metallic thallium and several of its salts, also a fine sample of hyposulphite of lime in very large and perfectly formed crystals, suggestive of the applicability of this salt to photographic use. The aniline dyes were exhibited in the form of costly masses and large crystals by Mr. W. H. Perkin and by Messrs. Nicolson and Maule. The new chloride of silver battery, invented by Messrs. De la Rue and Müller, was shown in action, and gave a brilliant electric light between carbon points separated a quarter of an inch. A variety of optical instruments were exhibited by Messrs. Horne and Thornthwaite, Murray and Heath, W. Ladd, R. and J. Beck, and J. Browning. The last-named gentleman showed, in comparison with bleed, the spectrum of a newly discovered crimson colouring matter, containing copper, extracted by Mr. Church from the wing feathers of the Cape Lory. Several large blocks of Iceland spar, showing widely separated images by double refraction, were exhibited by Mr. Ladd; and in a room adjoining were arranged a fine display of Geissler tubes, an ozono generator, and the new magneto-electric machine, deriving its power from permanent magnets bent in a circular form. Beside Sir David Brewster's old illusion of the "cylindrical mirror," was shown by Mr. J. Huggins, photographer, of Norwich, a new polarizing kaleidoscope, in which the ever-changing coloured figures were produced by moving plates of agate, mica, and selenite. Messrs. Beck had prepared a surprise by bringing the microscope to bear upon the frontispiece plate—a photograph—in Mr. Barry's work on the Architecture of the Houses of Parliament, by which the initials of Mr. Pugin were clearly discernable in certain portions of the ornamental design.

QUEKETT SOIREE.—The Quekett Microscopical Club held a soiree in the laboratory and museum of University College

last Friday evening. Upwards of a thousand visitors were present, and a very magnificent collection of microscopes and various other forms of scientific apparatus was exhibited. Mr. Solomon illustrated the value of the magnesium light in illuminating enlarged images of microscopic objects. The evening was altogether a great success.

ART EXHIBITION IN LANCASHIRE.—An intended exhibition of works of fine art, to be held at Darwen, in Lancashire, is announced to be opened in May. As photographs will form an important feature of this exhibition, those of our readers who have pictures worthy of public display will do well to contribute to what appears likely to be an important and interesting local exhibition. Communications should be addressed, without delay, to W. S. Ashton, Esq., Hon. Sec., Darwen, Lancashire. The object is to provide funds for establishing an Educational Institution in Darwen.

SCIENTIFIC EDUCATION.—The Committee of Council of Education at South Kensington have recently passed a minute granting scholarships for the encouragement of scientific instruction.

TEST FOR THE PRESENCE OF A FREE ACID.—Dissolve chloride of silver in just sufficient ammonia to make a clear solution. If a little of the test be added to ordinary spring water, the carbonate acid present in the latter will neutralize the ammonia and precipitate the chloride. The above forms a good lecture experiment, the test being a very delicate one.—*Chemical News*.

TO PRODUCE ETCHINGS IN IMITATION OF THE OLD MASTERS.—A "Practical Man" sends the following, which has been described before, but is still little known:—"Take a quarter or one-third glass plate, coat it with any kind of collodion, and then put it into the nitrate bath; allow it to remain for three or four minutes, then take it out and well wash it; stand it up to dry; when it is so—or appears to be so—give it a further dry and warm before the fire or over a spirit lamp; then lay on the table and trace your design as you would on a copper-plate; then work away with the etching point or needle, removing the dry collodion dust with a duster or small bellows (no blowing with the mouth); when finished, print in the pressure-frame as you would a negative. For ornaments, cards, or artistic bits, good imitations of etching may be produced at the cost and outlay of a few pence."

### To Correspondents.

PHOTOGRAPHY AND DISEASE.—A correspondent signing "Hypo (chondriac)" is disposed to have a good-natured laugh at those who attribute especially unhealthy influence to the chemicals used in photography, and seems to think that many of the symptoms described are traceable to ordinary causes. He says, speaking of his experience as an amateur:—"My symptoms were simply these. Once or twice in the course of last summer, after a day's outing with the camera, I have been visited by a most severe cold with all its attendant miseries; at another time with a violent attack of indigestion; and again, on one occasion, with a copious bleeding of the nose. Now I am fully persuaded that all these were but the effects of one or more of the chemicals—may be the collodion, may be the silver bath, or the hypo, which, either singly or combined, silently but surely invade the system. My matter-of-fact friends, to be sure, instead of giving me their sympathy for my martyrdom to the cause of science and art, would insist that the cold was but the consequence of my lying down on the damp grass after having worked myself up to fever heat in a broiling sun in the smallest of tents without a breath of ventilation; that my fit of indigestion simply arose from my having, at the end of a hard day's work, eaten too heartily after fasting since breakfast; and that, finally, the bleeding of the nose was due to nothing but my face coming into somewhat rude contact with the hand of a vulgar boor, whom I endeavoured to eject from my angle of view, persuasion having failed. But what can you expect from the ignorant, to whom our noble art is a dead letter? You, Mr. Editor, I am sure, will agree with me, that we must look for the true causes elsewhere, and that we must hold the collodion bottle responsible, until it has clearly proved its innocence, that that is the real culprit." As we pointed out in our comments on the first letters which reached us on this subject, many of the symptoms described by suffering correspondents are more legitimately attributable to inattention to ordinary hygienic laws than to the necessary influence of photography; but sufferers naturally enquire the cause of their sufferings, and nervous debility often depresses the invalid with "thick-coming fancies." We prefer to point

- out, where we can, remedies for the suffering, rather than to laugh at the sufferers.
- R. M. S.**—The design and proportions of your proposed studio seem excellent. We should use common 21-ounce sheet glass unground. The process of grinding destroys the power of glass to transmit light in an enormous degree (in some cases as much as 60 per cent.), and, except when exposed to direct sunlight, its diffusing power is not required. We believe that a very pale and delicate cobalt blue glass has some advantages; but, on the whole, we prefer the common sheet glass, as least liable to change, and, being the cheapest, its occasional renewal, if it change colour, is not a serious matter. M. Salomon, as we have stated in the *NEWS*, with a glass room of a somewhat similar character to that you propose, has the whole of the skylight stippled to give the effect of ground glass. This can be done at any time in your proposed studio if you find it desirable to subdue the top light permanently. Mr. Blanchard's plan of using starch obstructs less light than grinding or stippling with white paint.
- W. NORMAN.**—The second you mention—that is, the London maker—undoubtedly.
- JAMES CORNWALL.**—We cannot explain the circumstances, but will endeavour to take occasion to enquire. The work is, however, so little and out of date that it would be of comparatively little use to you. There may possibly be another edition prepared at some time; but there has been no new one for many years.
- EARNEST.**—Your proposed alteration on the south side of your studio will probably be an improvement. The chief error in your lighting arrangements appears to be the management of the north side light. One imperative condition of good light is to employ the use of *one* dominant light, and not a series of distinct lights; the varied patches of light formed by 1, 2, 3, 4 on the north side cannot give satisfactory results. Let the whole of the side light from 1 to 4 consist of clear glass, using blinds on sliding rods to circumscribe the area of light when necessary. The best lighted pictures of those you enclose are B, F, and G.
- H. E.**—Your question is much too indefinite to enable us to give you definite information. The cheapest way to go to work to build a glass house depends on so many circumstances. Much depends upon whether you intend to use wood, bricks, or iron, in conjunction with glass, or which you will be permitted to use by the District Surveyor, should you be amenable to such an officer. A simple oblong building of ridge-roof or lean-to form of the size you mention, 20 feet by 8 feet, may be erected for from £30 to £100, depending on strength, finish, position, and other circumstances. You will find 8 feet rather too narrow; 10 or 12 would be better. Decide upon your general requirements, and then consult a builder; and, after deciding upon details, get a contract.
- LIZZIE.**—We cannot give Lizzie any very satisfactory information, we fear. Mr. Day, of 20, Cockspur Street, was, during last month, gazetted as a bankrupt. How the subscribers to the Art Union for the distribution of chromo-lithographs will fare, we cannot tell.
- RHEUMATIC.**—Your Ross's triplet will answer well for enlarging. 2. Its focus, so far as we remember, is 8 inches; in which case, in enlarging a card to 20 by 15, the distance between the lens and focussing screen would be about 56 inches. 3. A "common French lens" is scarcely likely to be suitable for enlargement, unless it chance to be a very good one. 4. Without knowing the focus we cannot state the distance required between the lens and focussing screen; probably between 40 and 50 inches.
- TOMAHAWK.**—Your flatted backgrounds must not be wetted before placing on a frame; by a little skill you may stretch the canvas pretty evenly. Attach the whole of one side with tacks first, then stretch gently and attach the other side, and so proceed. 2. "Flatting" consists of oil paint ground with turpentine and the smallest possible proportion of oil which can be employed; it is applied in the same way as oil paint, but requires some manipulatory skill to secure an even surface. Two persons effect it best; one applying the paint, and another following with a "softener" to blend the brush-marks.
- BROMO.**—We have not before met with such spots, but will give the matter our attention, and, if possible, trace the cause.
- B. MAGIC.**—The result you enclose is very promising. Experience alone will enable you to arrive at the best results in any new application of this kind. Possibly printing the image on glass, and then, when all the processes have been completed, transferring the film to wood, might answer, and prevent the surface of the wood becoming rough.
- L. S.**—In an English inch there are about 25 millimetres. A metre is 39 inches, a centimetre is one-hundredth part of a metre, and a millimetre one-thousandth part. About 2½ centimetres make an inch; and, of course, about 30 centimetres make a foot. We state the proportion in round numbers to avoid minute fractions. You will do well to familiarize yourself with the metrical system, which is that most commonly used in scientific statements of measure.
- H. A.**—Permanganate of potash may be used for removing organic matter from printing baths, as well as negative baths. Mr. Johnson objects to Condry's fluid for the purpose as being often impure; in our own practice we have met with tolerably pure samples, and should not hesitate to use it when the permanganate in crystals was not readily accessible. 2. The fixing bath mentioned in the article to which you refer is exceedingly weak; weaker than we should recommend. The reason why a weak fixing bath is there thought sufficient is, we presume, that in the other part of the formula the solutions are weak; and the less silver salt in the paper, the weaker may be the bath in which the prints are fixed. When a sulphocyanide bath is used for toning, a somewhat weaker fixing bath may be used. 3. The experience of the gentleman who warns you against intensifying with pyro and silver preceded by iodine, and recommends bichloride of mercury as giving a more stable negative, is exceptional, and we cannot advise you to accept his advice. We have not found any deterioration in negatives intensified in the first-mentioned manner.
- W. J. A. G.**—Mr. Claudet did make a lens of topaz; but did not, we believe, get the diamond lens made, as he intended, had he lived. Prints from a negative taken with the topaz lens will be presented to the members of the Photographic Society. 2. The lens you mention, if it work well, is undoubtedly cheap at the money. You must bear in mind, however, that the whole-plate lenses of French opticians are rarely larger in diameter or longer in focus than the half-plate lenses of English opticians.
- J. W. H. A.**—Oil cloth or kamptulicon is best for the floor of a studio, because they may be easily kept clean and free from dust. Carpet or cocoa-nut matting may be used, but require more care to prevent the occasional annoyance of dust. The colour of the matting would not be too light, unless a strong top light fall upon it.
- M. WANE.**—We regret that we cannot give you definite information as to the period of receiving contributions at the Leeds Exhibition.
- TOP-LIGHT.**—We should suppose that the defect to which you refer—namely, the faces being flat and white, and the drapery too dark—was due to slight under-exposure. The white calico diffuses the light throughout the rooms, but prevents direct light reaching the model.
- D. S. (Aberdeen).**—The decision as to the method of enlarging much depends on the results desired, and the appliances and skill you possess. If you wish to enlarge small negatives, up to (say) 12 by 10, then the process upon collodion and transferring is good. If you wish for more extended enlargements, the production of enlarged negatives, or the use of the solar camera for producing enlargements on paper will be better. In all such matters it is impossible to say that any special method is the best, as each is qualified by circumstances, and each photographer must determine for himself. Try the enlargement on collodion, and then transfer; this is simple, and requires but little apparatus beyond what all photographers possess. 2. If you succeed well with the acetate bath, do not change. We described the sulphocyanide bath as giving special results suited to special circumstances, but not as preferable for general use to the acetate bath. We prefer the acetate to the phosphate. 3. We do not think that the small miniatures you mention will ever become a rage, and they could scarcely be of much importance commercially if they were. We cannot write private letters in answer to photographic queries: our time is too fully engaged.
- W. H.**—A properly finished Daguerreotype does not fade; but it may become obscured by tarnish by exposure to the atmosphere. This tarnish may be removed by cyanide. First wet the plate and see that the water flows freely over it; sometimes alcohol is necessary to secure this; then, when the water flows without appearance of greasiness, apply a 10-grain solution of cyanide, which will quickly remove the tarnish; wash well, finishing with distilled water, and dry off with a spirit lamp. This is an operation best performed by a person familiar with Daguerreotype manipulation.
- W. J. L.**—We fear that we have no correspondent at Vienna to whom we can address such enquiries, but will see if opportunity serve.
- R. H. COURTENAY.**—Thanks.
- J. L.**—The exposure of 90 minutes with a wet plate in landscape photography to which you refer is, of course, absurd; the statement is doubtless an error of the writer, who has a very imperfect knowledge of such matters. 2. All the paragraphs you name are unacknowledged extracts from our own columns. 3. Probably very speedily.
- HENRY SPINK.**—We presume that transfer paper can be obtained of dealers in lithographic materials, such firms as that of Hughes and Kimber, for instance. Your letter in our next.
- B. B. L.**—There are occasionally other injurious sulphur compounds in cards besides hypo. We shall have something to say upon the subject shortly.
- Several Correspondents in our next.
- Several articles in type are again compelled to stand over.

### SEL CLEMENT, OR PRESERVATIVE NITRATE OF SILVER.

WE noticed some short time ago the introduction of a new salt of silver under the name of "Sel Clement Preservative Nitrate of Silver," intended for use in printing. Besides being offered at a price not exceeding three-fourths of that of pure nitrate of silver, it was stated to possess certain specific advantages over that salt, especially in the fact that paper prepared with it would keep sensitive for some time without deterioration. In estimating the economy of any new preparation offered in place of the ordinary salts of silver there is one conclusion at which we must inevitably arrive; namely, that half-a-crown's worth of the new salt cannot possibly contain more than half-a-crown's worth of silver; but as it is by no means impossible that this silver may be in combination with other bodies which aid the production of good results with the consumption of a small amount of silver, it cannot be asserted, without experiment, that a new salt is not economical. It is certain, therefore, that a novelty promising desirable results is worthy of trial.

We examined a sample placed in our hands, and ascertained that it contained nitrate of magnesia as well as nitrate of silver, which fact we announced. We then placed a portion of the salt in the hands of a distinguished chemist, who is a member of our staff, for careful quantitative analysis. From his report we learnt that the salts of silver and magnesia appeared to have been mixed in about equal proportions. Feeling that it would be unfair to the manufacturer to make known the results of an analysis of his preparation before it had been fairly tested by the public, who might be prejudiced by a statement that less than one half of the new salt consisted of nitrate of silver, we forbore, for the time, to publish the details of our examination, resolving to test the salt in practice, and also to learn the result of other experience before making further comment on the subject.

A contemporary has, however, relieved us of the necessity for further reticence by having published an analysis, from which it would appear that the example under examination contained only about one-third of its weight of nitrate of silver. It may be fair to the manufacturer and of interest to our readers that we should publish the result of our analysis, which is somewhat more favourable to the purchaser than that of our contemporary. We give it in the form we received it from our analyst a couple of months ago. It is as follows:—

"The *Sel Clement* submitted for examination is a mixture of salts, somewhat moist, white in colour, deliquescent, and very fusible. Reaction to litmus paper slightly acid. It consists of—

Nitrate of silver ... ..	46
Nitrate of magnesia ... ..	33
Water ... ..	21

100

"The salt contains a trace of iron, but no nitrate of soda, saltpetre, or zinc salt. It is impossible to drive off the water by fusion without decomposing some of the nitrate of magnesia, which then becomes partly insoluble in water.

"The nitrate of magnesia bears no definite atomic relation to the nitrate of silver, its amount standing between one and two atoms to one equivalent of the silver salt."

Our sample, it will be seen, contained 46 per cent. of silver, whilst that of our contemporary is only stated at 34.5 per cent.

A somewhat singular circumstance remains to be stated. Dr. Phipson, the English correspondent of the *Moniteur de la Photographie*, mentions in his letter the fact that the salt which had been recently introduced into this country contained nitrate of magnesia, and makes some comments thereon. The inventor of the *Sel Clement*, of whom the Editor speaks as a chemist of well-known reputation, writes a long letter to that journal, complaining of what he considers an unfair criticism of his invention by the English correspondent. With reference to the statement that the new salt of silver is nothing more than a mixture of nitrate of silver with nitrate of magnesia the inventor refuses to enter into a discussion as to whether these two salts combined exert a more beneficial effect than the silver salt alone, but states that, besides the salts just named, the *Sel Clement* contains two other substances which are organic, of which one is combined with the silver in the form of a salt, and is slightly sensitive to light, while the other possesses the preservative principle, and preserves the whiteness of the paper. "What are these two substances?" asks the inventor. "Seeing that they are organic bodies, it will be difficult to discover their nature by means of chemical analysis, and they can only be detected either by chance or by researches continued in a certain direction." After some discussion of the question of novelty, in which he states his conviction that the nitrate of magnesia had never "been suggested, except for the preservation of sensitive collodion, and not for paper," he proceeds to defend his right to keep the constituents of his material secret, at any rate, until he has indemnified himself for his labours. He does not pretend to any grand discovery, or seek to obtain honour and glory from his invention; he states that he merely asks for an impartial trial of a material which possesses certain special advantages; and if the salt fulfils the expectations of the buyer, he is fully content. He concludes by deprecating the tendency of the photographic world to consider any newly introduced material which is brought under the notice of the public as nothing better than quackery, and refers to the respectability of his agents as testifying to the genuineness and soundness of his product.

The question of the inventor as to the other constituents of his salt assuming the form of a challenge, we felt deserved a reply, and having discovered no indications of organic

matter in the sample in our possession, we consulted the gentleman of our staff to whom we have already referred, as to any indication of an organic compound in the sample submitted for his examination. Here is his reply:—

"MY DEAR SIR,—The sample of *Sel Clement* received from you on 1st February does not contain a trace of any organic substance. I prove it in this way:—All organic matters contain carbon, and give rise to the production of carbonic acid upon being fused with nitrate of silver. Quarter of an ounce of the *Sel Clement* was introduced into a test tube, fitted with a cork and small delivery tube, heated to fusion, and maintained for a considerable time in that state. The reddish vapours and all evolved gases were conducted into lime water contained in another test-tube. Not a trace of carbonic acid came over, for no precipitate made its appearance in the lime water.

"In order to ensure the existence of proper conditions under this negative experimental result, a small particle of sugar (less than one grain) was introduced into the apparatus, the cork replaced, and the fusion of the *Sel Clement* continued, when ample evidence of the production of carbonic acid was obtained by the immediate formation of a precipitate in the lime water.

"In affirming that *Sel Clement* does not contain organic matter, I would go further, and say that, even if organic matter were added in the course of preparation, it could not long survive the action of the boiling liquid at the time of evaporation. Again, if the crystals of *Sel Clement* really contained organic matter—such as sugar, citric acid, or other preservatives—in admixture, they would be alterable by exposure to sunlight, which is certainly not the case in that in my possession.—I am, dear sir, yours, &c.,

"March 18th, 1868."

"THE ANALYST."

All questions of the constitution of the salt apart, however, we think that the impartial trial for which the introducer asks should be fairly accorded to it. Our own experiments have not been sufficiently extended for a definite opinion; but we may remark that a 30-grain solution certainly gave better results than a 15-grain solution of nitrate of silver, and showed no tendency to dissolve the albumen. The paper so prepared also kept well; but it was somewhat less sensitive, and gave less vigour than a 30-grain nitrate solution containing sugar. The salts afford strong evidence of the value of nitrates—such as those of soda, ammonia, potash, or magnesia—when added to the nitrate bath, and so confirms the experience of many practical men, which has been contemned by a few theorists.

It may be worth while to mention that nitrate of magnesia was proposed as a preservative as early as 1854 by Messrs. Spiller and Crookes, for use not only with collodion plates, but also for use in paper, in conjunction with nitrate of silver in the Talbotype process.

#### DRY PLATES WITHOUT PRESERVATIVE.

The use of dry collodion plates without any preservative has been often proposed, and although tried from time to time with some degree of success, from some uncertainty as to the conditions upon which this success depends, the process has never been extensively adopted. To those who have experimented in this direction it has been tolerably clear that the quality of the collodion materially influences the results. One sample of collodion, simply washed and dried after exciting, will yield a clean, bright negative; whilst another, treated in all respects in the same manner, yields a thin, fogged, imperfect image; yet both samples have worked well in the wet process.

At the last meeting of the French Photographic Society M. Romain-Talbot detailed the manipulations necessary with a collodion prepared by M. Harnecker, in which the plate is simply thoroughly washed and dried after exciting. The nature of the collodion is not stated, but it seems probable that it consists in the addition to the collodion of some trace

of an organic substance capable of combining with silver, or that the collodion is prepared from a sample of pyroxyline in which a trace of nitro-glucose has been formed in the process of manufacture. The prints exhibited to the meeting were from negatives produced on plates which had been kept for six months, thus indicating excellent keeping qualities. The formulae and manipulations given by M. Romain-Talbot for employment with this collodion are as follows:—

*Preparation of the Plates.*—Clean the glass with care, collodionise in the usual manner, and, when the last drop of it has nearly evaporated, plunge it for four or five minutes into a bath composed as follows, keeping the plate in motion:—

Nitrate of silver	...	...	15 grammes
Distilled water	...	...	150 "
Pure nitric acid	...	...	1 drop.

This bath, it will be seen, contains nearly fifty grains of nitrate of silver to the ounce, and possesses an unusually large proportion of nitric acid, which renders it probable that a large proportion of a bromide is employed in the collodion.

When the plate is taken out of the bath, allow it to drain; wash it with distilled water; wash further with ordinary water, and finally with filtered or distilled water. If the plate be not well washed there is risk of a bad negative; good washing is, therefore, an essential condition; and should the water be of a calcareous nature, it is recommended to use distilled water only. Dry at a temperature of about 90° Fah. Thus prepared, the plate will keep during many months.

*Exposure.*—Twice or three times as long as the wet plate.

*Development.*—Plunge the exposed plate for from five to ten minutes into a bath of distilled water, and from thence into the silver bath above described, plunging the plate in and out four or five times; and then develop with a solution composed of—

Sulphate of iron	...	...	75 grammes
Water	...	...	1,800 "
Glacial acetic acid	...	...	45 "
Absolute alcohol	...	...	60 "

When all the details are well out, wash well and continue to develop with a solution of—

Pyrogallie acid	...	...	1 gramme
Distilled water	...	...	225 grammes
Glacial acetic acid	...	...	10 "

To which is added—

Nitrate of silver	...	...	1 gramme
Distilled water	...	...	48 grammes
Glacial acetic acid	...	...	1 gramme.

Continue with the last solution until the negative shall have acquired the strength desired.

*Fixing Bath.*—

Hyposulphite of soda	...	...	1 gramme
Water	...	...	3 grammes.

Finally, coat with a dilute solution of gum, and dry the plate.

#### Critical Notices.

PHOTOGRAPHIC OPTICS: including the Description of Lenses and Enlarging Apparatus. By D. VAN MONCKNOVEN, Doctor of Science. With Five Plates and Eighty-seven Woodcuts. Translated from the French. (London: Robert Hardwicke.)

It is a true remark, which has been oft repeated of late, that in photography the progress of practice has continually outstripped that of theory. Processes have been long practised with skill, and attended with success, the rationale

of which is still but imperfectly understood. What is true in the chemistry of photography is true in relation to its optics. We do not mean to assert that opticians have worked by rule-of-thumb rather than by mathematical knowledge, although that position might possibly, in some degree, be justified; but we mean that many photographers have acquired some knowledge of the use of lenses, and of the application of special lenses to special purposes, without the slightest knowledge of their construction or of the reason why a lens excellent for one purpose failed in another, or of the principles upon which their selection of lenses for various uses should be based. Dr. Van Monckhoven believes, —and, we fear, with much reason—that the knowledge of how to use a lens is “a thing about which ninety-nine photographers out of a hundred are in ignorance,” and adds, that “to use a lens improperly is to produce portraits false in perspective, buildings and houses falling into the street,” &c. It is tolerably certain that more ignorance prevails in regard to the optics of photography, even amongst cultivated photographers, than in regard to any other of the multifarious branches of knowledge requisite to constitute a really good photographer, and that any work which may aid to dispel that ignorance should be hailed with welcome by the photographic community.

Dr. Van Monckhoven's treatise on photographic optics was issued in French about two years ago, and is now introduced by Mr. Hardwicke to photographers in an English dress. No translator's or editor's name is appended to the work; but, with the exception of the insertion, in one instance, of a foot-note by the Editor, attempting, but erroneously, to correct the author, the work seems very well done.

We need scarcely remark that the task of producing a work on optics for photographers was an exceedingly difficult one. It was necessary to preserve scientific accuracy, and it was not less necessary to deal with the subject in a popular manner; and in attempting both, the work ran the risk of being pronounced superficial by scholars, and abstruse by the unlearned. Nevertheless, without sacrificing precision—some few doubtful positions excepted—Dr. Van Monckhoven has endeavoured to write a popular book, and has produced an addition to the text-books of the art which every photographer ought to possess.

The work is divided into two books: the first treating of optics and lenses, as applying to the ordinary practice of photography; and the second of the apparatus and processes employed in enlarging.

The early chapters of the first part are devoted to a statement of the known laws of light and of optics generally, treated with especial relation to photography, and furnishes a succinct account of the history, quality, and construction of the various lenses now in use. The various aberrations—spherical aberration, chromatic aberration, curvature of field, distortion, and astigmatism—are carefully considered, in connection with their causes and cure, and the relative degree in which they each prevail in different kinds of lenses, the copious use of diagrams tending materially to aid the student in a perfect understanding of the author. After treating fully of the aberrations of lenses, the author proceeds to the classification of lenses under two distinct heads, the *aplanatic* and the *non-aplanatic*, the former giving sharp images over a small field with their entire aperture, and the latter, requiring stopping down, giving sharp images over a more extended field. It is in the treatment of this part of his subject that the author lays himself most open to the charge of shackling himself with theories the truth of which is not borne out in practice. Many of the new lenses which have been introduced of late, and which he classifies as non-aplanatic, he utterly condemns as a retrograde rather than an advancing step in photographic optics. All single combinations come under this sweeping condemnation, as well as some other lenses which possess a high popularity amongst photographers. The reason alleged is as follows:—

The practice of photography has established that, when the

image at the focus of a lens is wanting in intensity, the photographic reproduction of this image is itself wanting in relief, the foregrounds being too black, the objects situated in the horizon confounded with the sky, and the clouds in the sky replaced by a plain ground of uniform tint; the proof, in a word, is wanting in aerial perspective, and, if it be a portrait, in vigour and relief. For, to give sharp images, non-aplanatic objectives require very small diaphragms, and generally of from  $\frac{f}{40}$  to  $\frac{f}{72}$ ,  $f$  being

their focal length: hence an insufficient intensity in the image and the defect which we have just pointed out. But, exempt from distortion, and including a considerable angle, they are useful in some special cases, such as the reproduction of cartes, buildings situated at a very short distance, or landscapes and buildings strongly illuminated by a powerful sun.

Aplanatic objectives, under the head of which rank the *triplet*, include a less angle, but do not require diaphragms exceeding  $\frac{f}{30}$ ; and therefore they give more artistic photographic

proofs, in which the foregrounds and the horizons are well brought out, and the skies have clouds. If the light is insufficient, they are employed with a larger diaphragm; and the sharpness of the image is not destroyed as with non-aplanatic objectives, but only limited to a smaller field. They can be used for portraits in the open air, groups, and animated scenes, with their entire aperture—an advantage which is invaluable in practice. Lastly, the angle they include, being between 50 and 60 degrees, is more than sufficient, because, if this angle is more considerable, the effect of the perspective is doubtless more astonishing than agreeable.

In our opinion, therefore, the use of non-aplanatic objectives—such as the *single lens*, the *globe lens*, *Mr. Ross's doublet*, and that of *M. de Steinheil*—should be abandoned (except in some special cases, which we have enumerated above) for that of aplanatic objectives, among which the *triplet* is the best, as being free from distortion.

Whilst fully endorsing the author's views as to the excellence of the triple, we take exception to his wholesale condemnation of many of the lenses the abandonment of which he recommends. For landscape purposes, many of our best practical photographers prefer the use of a good ordinary single lens; the wide-angle-single lens, and the rapid stereoscopic single lens of Dallmeyer, are justly regarded as amongst the most useful instruments placed in the hands of photographers; and the reputation of the doublet of Ross is justified by the numerous admirable photographs produced by it, and brought from time to time under the attention of photographers. The author's position, so far as it is confined to a recommendation to the use of lenses giving good definition with wide apertures, we most cordially support, and agree with him that lenses requiring small stops to secure definition should be abandoned, as, besides the protracted exposure involved, the pictures produced are flat, tame, and unsatisfactory. It is only to his sweeping condemnation of all lenses alike which come within his theoretical classification as non-aplanatic that we take exception.

But whilst strongly expressing his leaning, on theoretical grounds, to the lenses he classes as aplanatic, the author is strictly fair and just in his description and treatment of the various lenses in detail, dealing with the subject in a spirit of scientific impartiality which is highly commendable.

The practical portions of the book will be read by photographers with the greatest interest. Here is an example relating to a subject to which the attention of photographers has of late years been much directed, but which is by no means yet exhausted:—

*Depth of Focus.*—Depth of focus is the property of lenses of giving a clear image in planes of which the distance is unequal. It follows from this that the ground-glass placed at the focus of a lens may be moved to a very slight extent without the image sensibly losing its sharpness.

To prove this experimentally, bring a camera furnished with a single combination to bear on a landscape. Bring to a focus the objects farthest off. We shall soon remark two things: the first is, that the ground glass can be advanced or withdrawn to a small extent without the sharpness of the image of a fixed plane of the landscape sensibly changing; the second is, that if we bring to a focus the most distant plane, many other nearer planes will still be in focus.

The same experiment can be made with an opera-glass, which may be regulated for distant objects so as that they may be seen

very distinctly. If you now direct the glass to nearer objects you will also see them with perfect clearness. Similarly, by holding the opera-glass directed on a distant object, you will see that you can move the eye-piece a short distance without lessening sensibly the sharpness of the image by doing so.

It is to be observed that the depth of the focus varies with the

FIG. 44.

FIG. 45.

aperture of the lens. Figures 44 and 45 make this very plain. In figure 44 we make use of a lens with its entire aperture. The rays,  $r, r$ , emanating from a distant point, form, after having traversed the lens  $D$ , the image of the point at  $a$  on a screen or ground glass  $A$ . But if the ground glass be either drawn back or advanced, to  $C$  or to  $B$ , for example, the image of the point immediately spreads out in a circle, because angle  $a$  is very large. When the same lens,  $D$  (fig. 45), is reduced to its central part by a stop, the image of the point is still formed at  $a$ , but the ground glass can be placed at  $C$  or at  $B$ , without the image of the point becoming now appreciably altered. This is because, in fig. 44, the rays,  $r, r$ , emerging from the lens, are much more convergent than in fig. 45.

It results, therefore, from the preceding, that a convergent lens is capable of giving a sharp image of planes distant from each other, contrary, apparently, to the law of conjugate foci. But experiment shows that it is only on the condition that these planes are sufficiently distant from the lens that their image may be formed near the principal focus. Thus, the nearer objects approach the lens, the less becomes this depth of focus, as is shown by the following short table, which gives the focal lengths of a lens of 10 cent. focus, for objects of which the distance is constantly diminishing:—

Distance of object.	Elongation of focal length of the lens.
10,000 metres	0.001 millimetres
1,000 "	0.01 "
100 "	0.1 "
50 "	0.2 "
10 "	1.01 "
5 "	2.04 "
4 "	2.6 "
3 "	3.5 "
2 "	5.3 "
1 "	11.1 "
50 centimetres	25 "
40 "	33.3 "
30 "	50 "
20 "	100 "

This table is very instructive. It enables us to see clearly that for objects 50 metres distant, for example, the focal length of the lens is increased only two-tenths of a millimetre, a length quite inappreciable; for 10,000 metres it is increased still less, only a thousandth of a millimetre. Therefore, all objects situated more than 50 metres from the lens will be in focus on the ground glass, however great may be their distance.

When, on the contrary, the object is situated very near the lens—for example, 30 centimetres from it—the ground glass has to be drawn out 5 centimetres; when at 50 centimetres, the glass has to be drawn out 2½ centimetres; when the object is distant one metre, the glass has to be drawn out 11 millimetres—quantities relatively great. For this reason, objects situated at a short distance from the lens give sharp images only on the condition that they are very near each other; hence the difficulty of obtaining the image equally sharp if this condition is not fulfilled.

Thus, then, the depth of focus of the lens varies with its aperture and the distance of the objects which form the image at its focus. It varies, also, according to the form of the lens or the optical combination of lenses composing an objective. Convergent meniscus lenses have the greatest depth of focus when their concave face is towards the objects. Among objectives composed of several lenses, the *orthoscopic* has the greatest depth of focus, and the ordinary *double combination* the least. This is because the former has generally a small aperture in relation to its focal length, and because, moreover, the divergent lens placed along with the anterior convergent lens renders the emergent pencils less convergent. The second, on the contrary, has generally a very large aperture, and besides, the rays emergent from the first lens (the one which is towards the object) are rendered still more convergent by the second lens.

After giving a full description of the various forms of photographic lenses in use, the mode of using photographic lenses receives attention, after which the author proceeds to

the subject of enlargement, a subject he has pre-eminently made his own, and demonstrated by the production of some of the finest enlargements which have ever been brought before the public. In this part of the book the processes and modes of working receive attention as well as the apparatus to be employed, and much valuable information is conveyed to which we shall probably return on a future occasion.

In the meantime, we remark that the work is one which every photographer ought to possess and study, and that the photographic world is deeply indebted to Dr. Van Monckhoven for the production of such work, and to Mr. Hardwicke the publisher for presenting it to English readers in an admirably neat and perfect form.

## VENTILATION OF DARK ROOMS.

MR. CHAS. WAGER HULL, in the *Philadelphia Photographer*, commenting on Mr. Cherrill's plan for ventilating dark rooms given in our last volume, says:—

"On reading and examining it, I was convinced that the plan alluded to of curing the evil would add another to the long list of the photographer's troubles, which, though it might save his health in one way, would injure it in another by spoiling much of his work, make him mad, ruffle his temper, cause him to say 'naughty words,' and generally be productive of bad consequences. If we are to have ventilation in our dark rooms, it is well for us to have not only good wholesome air, but, as well, air not charged with dust, which would be the case if introduced, as is proposed, in the article referred to, and which most certainly would be the case if brought in from out of doors. Imagine a current of air passing into our operating-room in midsummer, when everything is dry, and all the lighter particles go floating about through space, in entire disregard of eyes, nose, ears, or as, in this instance, dark rooms.

"By the introduction of this air into the dark room, I claim that though the physical health of the operator might be benefited, his moral health would be injured, his work would be spoiled; therefore, of the two evils, choose the least, of which choice there can be no doubt. 'How shall we better this plan?' the reader may be asking. Very easily, and thus: Do away with the door of your dark room, and, in its place, build up a crooked sort of an entrance, as seen in the ent following.

"By this simple plan all light is cut off from the entrance, and the room is as well ventilated as need be, without the troubles which are certain to come from the plan first alluded to.

"You enter at A, and, turning to the left, pass through B, and enter at C into the dark room D. By this simple arrangement you do away with the door, the constant opening and closing of which raises, during a busy day's work, enough dust to produce pinholes *ad libitum*.

"To my knowledge, several rooms built after this plan are an unqualified success. If any reader imagines that the light can possibly get into his room (which I do not), then let him make his passage B wide enough to put a partition

half-way across said passage as seen at E and F, and paint the inside of an orange or yellow colour. Should light enough to do injury get in after this addition, then blame the writer."

### ON COLLODIO-BROMIDE.

BY W. B. BOLTON.

In opening this subject, I do so more in the hope of inducing others to try collodio-bromide than with the intention of introducing anything new; for though much still remains to be done before the process will be perfect, so much has already been accomplished that in the present state of photographic knowledge there is, I fear, little chance of any considerable improvement being made either in this or other processes; and until new materials are utilized, or new methods of applying the old ones discovered, we must be content to take things as they are. At the same time there is no reason why we should incur unnecessary trouble in any of our operations when the means are at hand of dispensing with that trouble; and it is certainly bad policy to occupy the whole of a fine summer's evening pent up in a stifling dark room, with the temperature almost at fever heat, preparing half-a-dozen or a dozen dry plates for next day's use, when the same may be easily and comfortably finished in half an hour, and equally good results expected.

The one advantage which collodio-bromide has over all other dry-plate processes is the extreme simplicity of all its operations; and the saving of time and trouble is a matter of the greatest importance, especially to those who have not much leisure to devote to photography. Amateurs, as a rule, belong to this latter class, and to them, therefore, it offers peculiar advantages. If a person takes up photography as a recreation, his aim should be to make it as much like enjoyment and as little like work as possible; instead of which some seem to try the very opposite plan. What would be thought of a man who, of his own free will, spent his leisure time in stone-breaking, that is supposing him not to be a geologist? or of another, who had a passion for voluntary exercise on the treadmill? There are many, I know, who do both under compulsion, but they are not to be considered as amateurs.

Most of my readers have, at any rate, a slight acquaintance with collodio-bromide, and do not, therefore, require to be told that it consists of collodion holding bromide of silver in suspension. The idea of dispensing with the use of the bath by using a collodion containing the sensitive silver salts is, I believe, very old, collodion containing iodide of silver having been used several years ago, and almost simultaneously with the publication of the collodio-bromide process in 1864; then Liesegang published his experiments with a similar process, based upon the formation of iodide of silver in the collodion, but found it unsuitable for negative work; indeed, it was not until bromide was substituted for iodide that any success was obtained. For some time it seemed doubtful whether the process would ever become popular, and up to last year its use was confined almost entirely to a few Liverpool photographers; but now, thanks to the exertions of Mr. Mawdsley, it has been so practically worked out as to bear comparison with any of the standard dry-plate processes of the day. And now to proceed to details.

We will commence with the collodion, as being the most essential part of the process. Though scarcely so dependent upon the collodion as most other dry processes, there are still certain requirements to be fulfilled if any degree of success is to be attained. The most important thing to be looked to is the age of the collodion; before it is of any use it should possess that quality, or combination of qualities, generally termed "ripeness." The length of time required to ripen it, of course, depends upon the bromizing salts. I have found very little difference in the results obtained by different formulæ, provided always the collodion was of the requisite age; I do not care how old it is, as long as it is old enough.

The formula I generally work with is 6 grains of bromide of ammonium and 4 to 5 grains of pyroxyline to the ounce of collodion, the ether and alcohol in equal parts. This requires no more than two or three weeks to put it into working order. Mr. Mawdsley's formula I do not know exactly, but bromide of cadmium is the prevailing feature. My reason for preferring the bromide of ammonium to that of cadmium is the peculiar effect the latter salt has in rendering the collodion glutinous, which effect is only partially removed by age. It is of the utmost importance that the collodion should be as structureless as possible, for the horrors of a mottled or crapy collodion are doubly magnified in the collodio-bromide process. It is a well-known fact that if the ether predominate over the alcohol, the collodion will give a strong film, but very much inclined to mottling and crappiness; an excess of alcohol, on the other hand, gives an open structureless film, more liable to break away in the operations of washing and developing, and also more sensitive. I consider it a mistake, therefore, to use the ether in excess, but would rather incline to the opposite course, the only objection being the difficulty of keeping the film on the plate, which is easily obviated by the use of a substratum of albumen or india-rubber. The former I prefer, as there is no bath to contaminate, and it does its work much more effectually than india-rubber, and the trouble is so very small that it need scarcely be taken into account.

With regard to the salts used in the collodion I may, perhaps, say a word or two. Cadmium and ammonium are at present the only ones used, but I see no reason why the list should not be extended to two or three more, the bromides of lithium and magnesium amongst the number. The latter, which is a very unstable salt, rendering the collodion very limpid and structureless, might with advantage be used to counteract the opposite qualities of bromide of cadmium.

The quantity of silver used in sensitizing the collodion will, of course, vary according to the formula, in consequence of the difference in the atomic weights of various bases. A collodion containing 8 grains of bromide of cadmium, which may be taken as the standard quantity, would require, according to theory, exactly 10 grains of nitrate of silver to combine with its bromine; but in practice it is found necessary to use a little more. With bromide of ammonium, of which the atomic weight is less, 6 grains would be about equivalent to 8 of cadmium, the exact theoretical quantity of silver required being 10.4 grains. The bromides of lithium and magnesium being still lower in the scale, would combine with the same quantity of silver in the proportion of 5.1 grains and 5.4 grains respectively.

The silver having been added, the next question is how long the collodio-bromide should be kept before use, and how long it will keep in a fit state for use. There are so many opinions on this subject that it is a difficult question to answer, most agreeing, however, that the sooner it is used the better. I find it to be in its most sensitive state about six hours after it is mixed, and I also find it impossible to do anything much with it when more than a few days old.

If the collodion be properly made, no substratum will be required; the edges, of course, must be tipped with india-rubber or albumen, but as a security against accidents it is better to take a little extra trouble and use the substratum. A number of plates may be coated and packed away in a dry place until required for use.

Everything ready, my plates "tipped" or albuminized as the case may be, my mode of procedure is as follows:—Having first filtered the collodio-bromide lightly through cotton-wool, I coat the first plate. More care is required in coating a plate with collodio-bromide than with ordinary collodion; if the surplus be run back into the bottle too quickly, a streaky film is the result. The first plate is then laid down to set whilst the second is coated; number one is then transferred to a dish of clean rain-water, and number three coated, and so on, until the required number are

coated. I allow each plate to set for about a minute. When all the plates are coated and placed in water, I commence at the first one again, and put them through the tannin, on to the draining-rack, and then dry them.

If no more than a dozen plates are to be prepared, only one lot of washing water will be required, but for a larger number it will be safer to change it occasionally, lest the silver should collect to an injurious extent. When dry, the back of the glass is coated with annatto, and the plate is then ready for exposure.

For developing, the only solutions required are:—

No. 1.			
Strong liquid ammonia	...	...	1 drachm
Water	...	...	7 drachms
No. 2.			
Bromide of potassium	...	...	8 grains
Water	...	...	1 ounce
No. 3.			
Pyrogallie acid	...	...	100 grains
Pure alcohol	...	...	1 ounce

A mixture of alcohol and water may be kept also for moistening the plates before development. The first step is to remove the annatto, which is easily effected with a damp sponge or cloth; for this purpose it will be found convenient to have a frame of wood into which the plate can be laid face downwards so as to avoid touching the film.

The annatto removed, the plate is then covered with alcohol and water, and washed thoroughly. Then take a small quantity of water according to the size of the plate, and to each drachm add one drop each of Nos. 1, 2, and 3, which will, if the exposure have been rightly timed, bring out the picture very quickly. When all the detail is out, wash and apply another dose of developer containing two drops of Nos. 1, 2, 3, to each drachm. Should the second application not confer sufficient density, wash, and apply a third dose of the same strength as the last. Fix with hypo, and finish in the usual way.

That bromide alone is superior to iodide and bromide mixed, for dry plates, I think nobody will now deny. Its rapidity, its power in rendering detail in foliage or badly lighted subjects, and, above all, the improved method of development to which it is adapted, deserve the attention of every dry plate worker.

## PICTORIAL EFFECT IN PHOTOGRAPHY;

BEING LESSONS IN  
COMPOSITION AND CHIAOSCURA FOR PHOTOGRAPHERS.

BY H. P. ROBINSON.

### CHAPTER IX.

"It is sometimes admitted that the mere imitation of nature is not sufficient to make a picture, and that some art in the treatment is required, but nevertheless contended that students should confine themselves to the imitation, without any reference to the pictorial effect. But it will require a strong argument to support the position that amateurs should be limited to that portion which requires incessant application, and debarred from those licenses to make their productions agreeable which are freely admitted in the works of professed artists. Moreover, it is difficult to discover why the end should not always, and from the first, be kept in view.—Howard.

In making a pictorial representation of a scene from nature there are many particulars worth bearing in mind, some of which are self-evident, but which, for the sake of order, and for the information of those who have not arrived at even the elementary stage of art, may be as well mentioned here.

Parallel lines are objectionable. If the horizon is bounded by a straight line, the middle distance or foreground should be undulating. This is often easily managed by a change of position so as to get a perspective view of the foreground. A move of a few yards will often entirely alter the lines of a picture.

A front elevation of an object is seldom so picturesque as the same object seen in perspective. Figure 1 is from a stereoscopic slide, slightly exaggerated for the sake of making the defective composition more glaring. The parallel lines

of the towers are at right angles with the parallel lines of the river, and the alder bush occupies a prominent position in the centre: an arrangement than which nothing could be worse. A position taken forty or fifty yards along the bank

Fig. 1.

Fig. 2.

of the river would present a view as represented in figure 2, which entirely agrees with the rules of composition as set down in former chapters. Some writers argue that, because the artist is not greater than the Divine Maker of nature, he should make no attempt to improve or select nature. Now, photographs taken from either of the stand-points indicated by these sketches would be equally true, but figure 1 is probably the way in which these writers would represent the castle, and figure 2 is how the same object would be presented by an artist. I leave my readers to select which they would prefer.

However objectionable straight lines may appear when many of them run parallel with one another, a few straight lines are exceedingly valuable in a landscape, giving variety by opposing the more graceful curves, and presenting a feeling of stability in the picture. Sometimes a few parallel lines in the distance and sky afford a pleasing contrast to the undulating lines in the landscape. A small portion of straight line is often of extreme value in a picture containing many curves. The lines of a building on an eminence, or seen through trees, always add to the picturesque effect. In the interior of a cathedral or church the straight lines of the columns many times repeated give an idea of stability and solemnity to be obtained by no other way.

If a picture were divided down the middle, one half should never be a facsimile of the other. For instance, if a photograph were taken of the nave of a church from the centre of the aisle this effect would be produced. The repetition of the receding pillars produces grandeur, but the exact repetition of the same pillars on the opposite side would produce monotony. The same observations will hold good in a great variety of instances. A representation of a view extending down an avenue of trees, down a river, or down a street, as in figures 3 and 4, should never, if it is possible to avoid it, be taken from the centre. On a comparison of figures 3 and 4 the difference of result will be seen at a glance. The

Fig. 3.

Fig. 4

awkward effect of placing leading objects, such as the figure, cart, and church in figure 3, one above the other in a line, will also be apparent.

A picture should also always be properly closed in. The centre of an arch should never be left without any other support than the side of the picture, as in figure 5; but if no more of the landscape can be included the picture should finish at the abutment of one of the piers of the bridge.

No doubt the imagination of the spectator will supply the missing abutment or support, but it is very much better to show it in the picture. The same remark also applies to arches in interiors.

Fig. 5.

The choice of the position of the horizon is often a matter for serious consideration, but it may be taken as a rule that it should never be equi-distant from the top and bottom of the picture; that is, the plane should not be equally divided between earth and sky. The exact position—whether the horizon is above or below the centre—must be determined by the subject; but I have noticed that the majority of photographs seem to demand that the greatest space should be devoted to the earth; while, on the other hand, the majority of paintings and drawings have the horizon low. This difference may probably be accounted for by the fact that hitherto the sky has been a difficulty with photographers: first, because their endeavour has been to produce photographs so cheap that they could not afford to print in skies from a second negative; and secondly, because, although here is very little mechanical or chemical difficulty in the production of natural clouds when they exist, it is very rarely that a fine and suitable sky is found behind a landscape. It is scarcely probable that many persons, even of the timider sort, are deterred from introducing sky effects into their pictures by the objections of those who, to give some appearance of weight to their arguments, quote Ruskin, or, worse, feebly imitate him, failing, however, to catch his spirit or convey his meaning.

This subject is so important that I shall devote a future chapter to its consideration.

## RESEARCHES ON DRY PLATES.

BY M. CAREY LEA.\*

The investigations described in the previous papers have been continued at great length, and the effects of a great number of substances upon the "collodio-bromide" mixture have been studied. To attempt anything like a description of the results of each of these sets of experiments would take up too much space. Many scores—I might say hundreds—of plates were exposed, and it was found that a surprisingly large proportion of the substances tried, not merely conferred sensitiveness, but often a high degree of it. Of all these trials, which have cost very much time and labour, it is proposed here to give only the useful results. These were, first, the fixing of certain principles affecting all collodio-bromide work more definitely than heretofore understood; and, secondly, the discovery of two dry processes of a new character, and which leave little to be desired in facility, sensitiveness, and excellence of result. I speak of them as two processes; they are, however, but variations the one of the other, giving, however, very different results, adapted to different conditions. These processes are, in every way, so satisfactory, that I expect, in my own case, to use them henceforth exclusively.

### GENERAL OBSERVATIONS ON THE COLLODIO-BROMIDE PROCESS.

I have made a very large number of comparative trials of collodio-bromide plates, prepared in very many different ways, having taken great pains as to uniformity of exposure, selecting uniform light, timing accurately, and developing

the plates alongside of each other in pans filled with alkaline developer, which had been mixed in quantity and then poured into the separate pans, thus ensuring an exact uniformity of treatment, a precaution especially necessary in the comparative examination of dry plates, where differences in the plates and in their exposure may be so largely compensated by managing the development.

It has seemed to follow, from the results obtained, that the highest degree of comparative sensitiveness to weak light requires that the sensitizer employed should act on the film in the presence of free nitrate of silver; that is, a process in which the sensitizer has been applied in the presence of free nitrate of silver will give better detail in the shadows when the high lights have received just their proper exposure, than a process in which the plate has been washed previously to receiving the organic sensitizer. Consequently, softness will always be promoted by adopting a system in which the organic sensitizer has acted in the presence of free nitrate. Contrast and brilliancy will be promoted by first removing the free nitrate.

Whether this principle extends to other forms of the dry process besides the collodio-bromide I shall not now inquire; but I remark that, in the only dry process that has been regularly adopted and carried out on a large scale for the protection of negatives commercially, this principle of placing the sensitizer in contact with free nitrate of silver finds a place. I allude to that form of the collodio-albumen process used by Mr. England. I say this, not by any means as advocating the exclusive use of plates prepared under such conditions, but as affirming that, where the object is to secure softness, it is best attained in that way.

Another point to which my attention has been directed is the nature of the changes which a collodion salted with bromides only undergoes after the addition of nitrate of silver. It has been observed that when the nitrate of silver in fine powder is first shaken up with the bromized collodion, the latter, if poured on glass, is bluish and transparent. After a time it is found to have changed its character, and gives on glass a creamy and much more opaque film. Nitrate of silver dissolves very slowly in collodion, and the opinion has been, if I am not mistaken, that the change from the blue to the creamy condition marks the point at which enough silver salt had dissolved to saturate the bromide, and have an excess of silver present in the collodion.

This is very far from being the true explanation. A collodion may have a large excess of silver present in solution, and yet exhibit the blue condition. Conversely, it may give actual excess of bromide, and yet be creamy. In my opinion, the creamy condition results from an action of the bromide of silver upon the collodion itself. The following are the conditions under which it takes place:—

The creamy condition appears after an interval, which depends upon the temperature and upon the proportion of nitrate of silver in excess. The higher the temperature of the room the sooner it comes; and it comes faster in proportion to the excess of nitrate of silver up to a certain point; but if a very large excess of nitrate (relatively) is present, it comes very slowly, or not at all. Thus, when the collodion above described was sensitized with 20 grains of nitrate of silver to the ounce, representing an excess of  $6\frac{1}{2}$  grains, no indications of creaminess were visible after eighteen hours standing in a room with fire in it. One cause of this is, evidently, that where there is so much nitrate of silver present, the bromide of silver will not remain in suspension. For when the bromide of cadmium or other soluble bromide is in excess, the bromide of silver, as is well known, shows little tendency to precipitate, but remains for a very long time suspended. When the nitrate is in small excess, there is already much more tendency to precipitate; and when as much as 20 grains is added to a collodion of 8 grains bromide of cadmium and 2 grains bromide of ammonium, the bromide of silver settles, to a large proportion, within a few hours.

A curious fact is, that when the collodion has once passed

\* Philadelphia Photographer.

into the creamy stage it has very little tendency to return to the blue; so that, if more collodion be added in such proportion as to leave a small excess of bromide, the creamy condition still continues. I have had collodion in which there was one grain of nitrate of silver less than sufficient to saturate the bromide, and which was perfectly creamy.

These considerations are of no small importance in making dry plates of any sort by the collodio-bromide process; for the conditions of success are, that the film shall contain from 1 to  $2\frac{1}{2}$  grains of excess of nitrate of silver. Some have directed to use no excess of silver-salt, but to get the mixture as nearly neutralized as possible. I am satisfied that this is a mistake, and that the cleanest and brightest picture and most sensitive films are got with 2 or  $2\frac{1}{2}$  grains excess of nitrate. The creamy condition is also essential. Plates tried with even  $6\frac{1}{2}$  grains excess of nitrate and bluish films were very insensitive, and no good results could be developed on them.

(To be continued.)

### PHOTOGRAPHIC DIFFICULTIES OF AN AMATEUR IN SOUTH AFRICA.

BY DR. MANN.\*

It will make a brief, and possibly not unamusing episode, if I give another instance of the dash and boldness of my heroic pupil and friend. Upon one occasion we planned a visit to a wild district some thirty or forty miles beyond the then frontier of the colony, and still further beyond the houses of civilized men. We arranged that we would take some photographic apparatus with our pots and pans and everyday camp necessities; and in a fit of sublime resolution my friend resolved that he would work with no less pretentious an instrument than a whole-plate camera that he had recently imported from England. In order, however, that we might place ourselves beyond the reach of accident, we had two of the steadiest of our Kafir attendants told off, to be devoted exclusively to the charge of two of the most delicate of our impedimenta. One man carried, strapped over his shoulder, my mountain barometer, which on another occasion I had successfully and safely conveyed all round the colony in my travelling waggon. The second attendant bore over his back a large full plate glass bath, in the usual mahogany watertight case, filled with a precious fresh solution of the nitrate that we had prepared with the most consummate and careful skill for the occasion. At the end of our second day's march I found my mountain-barometer unpleasantly minus its mercury, which cost the instrument a six months' voyage to England and back for a new tube before it could be used in any service scientific again. I never learned what the process was by which my black friend had managed so soon to get his glass siphon emptied of its contents; but I have no doubt in my mind that the proximate cause of the result was the urgency of the caution which had been given him. He had been told that whenever he took the case off his shoulder he must never lay it down, but stand at ease, with his charge upright, one end upon the ground, until he was relieved of it by some duly qualified and accredited hand. In all probability, in making sure that he carried out his instructions in their full spirit as well as letter, he had struck the end of his case firmly down into the ground, to make doubly sure that it should not fall! In dealing with these amusing people, it is never possible to be altogether prepared for the grotesque and perverted views they take of the meaning and relations of the implements of white men. I once had a Kafir lad in my service who could not be brought to believe that the kitchen dustpan was not especially provided to cook his breakfast in.

To pass on, however, from the barometer to the bath. On the third day of our outward journey, when I was just recovering from the vexation the irreparable loss of my barometer had occasioned me, I was jogging along upon my horse chatting with my friend, our waggons and straggling cavalcade within easy reach behind us, when we heard a sudden outcry a little way behind; and on riding back to investigate its meaning, we found our bath-bearer struck motionless with fright, his burthen hanging from a stick over his shoulder, but the nitrate of silver solution running freely in streams down the lower

part of the blue striped shirt which constituted his livery. On relieving him from his load, we found the glass bath inside the mahogany case in three pieces, and the last drops of the precious solution just loitering amidst the fragments. The distress of the poor fellow at finding his back double-dyed with sable, as the sun, with its well-known impartiality, actinized the sensitized film of his cuticle, was one of the most ridiculous scenes that can well be conceived. At first we punished the unknown delinquency of our attendant by telling him the stain was of necessity ineradicable. But the effect of this punishment upon the member of a race which believes everything of this kind to have some "witchcraft" application was so severe that I was obliged to pledge my chiefly word that I would charm the stain away, so that no trace of it could be discovered, either naturally or supernaturally. A small stock of cyanide of potassium in the waggon enabled me to fulfil my pledge.

I must now confess that if the campaign had been entirely in my own hands after the destruction of our bath, I should have succumbed under the evil, and abandoned at once all photographic aspirations for that occasion. My friend, however, took the view that the pursuit of knowledge under difficulties is, in the end, quite as pleasant, and in some sense more profitable than walking the beaten road. We accordingly took stock of our appliances. We found that we had a small supply of dry nitrate of silver in our repertory, and, by an exhaustive overhaul of our camp equipage, we discovered that we had an enamelled iron dish in the kitchen department that had not more than half a dozen holes through the outer enamel. These we carefully repaired by a coating of sealing-wax. We next bent the largest pin we could find into a crook, and coated that too. We were free from all anxiety of strain in the matter of distilled water, for we had now learned that all the water in this part of south Africa is distilled. There is no trace of lime-salts in the greater portion of the country; and the frequent rain flows rapidly down through hard rocks of granite, slate, and sandstones, in so pure a condition that the natural stream can be turned to any use in photographic work. It is rare to find even the slightest perceptible trace of cloud on adding nitrate of silver to the liquid. For some years I took the trouble of distilling water for baths, developing solutions, and first washings, but for some considerable time have fallen back upon the merely settled and filtered water of the surface streams for everything, without discovering the slightest inconvenience. The large full plates we of course had to abandon, as your kitchen forecasts had never contemplated camp-stews of that dimension. But, by great good fortune, we had with us a small binocular stereographic camera; and with this and our enamelled dish and crooked pin, we worked throughout the expedition. I lay before the Society a series of the results of our practice, which, bad as they may be if judged by the high canons of photographic excellence, are interesting as records of the objects and scenes we encountered, and quite good enough to justify my heroic friend in his dogma that photography under difficulty, and in an iron dish, is better than no photography at all.

There is very little to say on the theme of development, excepting that the sulphate of iron developer, of medium strength (that is, comprising about 20 grains of the iron salt to the ounce of water) is the most pleasant to work with. It is of course necessary to give somewhat more than ordinary care to the manipulation of this part of the process, because the collodion film is almost always repellent of the solution, and unaccommodating to a troublesome degree, and abnormal deposit and reduction occur, in the high temperatures that have to be encountered, like a flash.

The gelatino-iron developer works most admirably, and is uniformly pleasant and reliable. I found Mr. Hughes's simple plan of dissolving a few grains of gelatino in the ordinary solution of the sulphate of iron serve every desirable end. I submit two or three small photographs produced with this developer at very high, and what would otherwise have been very unmanageable, temperatures. On account of the rapidity with which the undesired reduction takes place, it is unquestionably best to give full exposure to the plate, and to have as little to do with subsequent processes of intensification as may be. A weak solution of pyrogallie acid, with subsequent infinitesimal additions of nitrate of silver, is, I think, all that should ever be required.

Dry-plate photography is, beyond all question, eminently adapted to the circumstances that I have described as obtain

\* Continued from p. 141.

ing in lands situated like Natal. The plates keep excellently, can be carried about and played with even at the most unfavourable seasons, and may be developed days after their exposure. I have had dry plates, prepared in England after Hill Norris's plan, sent out, and have used them after I have had them months on hand, and very rarely experienced a failure. The best method of handling them, in my experience, was to give them full exposure, and then develop with a weak solution of gallic acid, until all detail was faintly apparent. The alkaline development is perfectly manageable, but, I think, not, on the whole, so satisfactory as the gentler treatment after full exposure. I submit pictures made from dried plates, prepared in England, and used months subsequently in South Africa. The exposure in these cases was twenty minutes in full sunshine. Both the albumen and tannin processes worked well. I preferred the tannin process as being the least troublesome; and I have no doubt that if I had used it more frequently, and made myself more familiar with its handling, I should have had little difficulty in getting very fair results. Liability to harshness and patchiness in the skies was the principal fault that occurred to me in my working; but this, I am quite satisfied, was due to my own want of care, and most probably of skill, in manipulating, and would be quite obviated with an extended experience.

If I return to my old haunts, I shall certainly fall back extensively upon Mr. England's simplification of the collodio-albumen process, and upon Mr. Bartholomew's acetate of morphine process, employing the one when requiring plates for three or four weeks' keeping, and the other when able to prepare the plates twenty-four or forty-eight hours before using them. I have not yet actually used either of these processes; but I am quite certain, from their description and the experience I have had with dry processes, that both would prove most valuable, pleasant, and certain methods of working in the conditions and circumstances I have named.

But there are obviously urgent reasons why dry-plate photography, even in its best and most sensitive forms, cannot be altogether relied upon to furnish all that the amateur requires during a lengthened sojourn amidst objects of interest in tropical or sub-tropical countries; and this remark at length brings me to the threshold of what I design to be the main point of this communication. Pending the fulfilment of Mr. McLachlan's promise, which, of course, I intend, in common with the rest of the photographic world, to avail myself of when the consummation is complete, I now incline to a direction of working which, if there be no concealed and latent objection not yet perceived, gives fair promise. I think, of turning the flank of the greater part of the difficulties that have to be braved. Upon a recent occasion I spent a few hours with my old friend Professor Piazza Smyth, of the Royal Observatory of Edinburgh; and on making a comparison of notes, he told me that for months he had struggled, both at Tenerife and in Egypt, with the same legion of troubles that I have described, and that he had finally only escaped from them by changing his own strategy. He then very kindly illustrated his entire process, and showed me a large series of results that he had achieved. Professor Smyth states roundly that, in his own old plan of working, he could never command, in high temperatures, anything like certainty of result; whereas, with his new plan of working he never fails. After a deliberate and careful examination of his plates taken in and around the Pyramids, and a subsequent review of all the circumstances of my own Natal experience, I have quite come to the conclusion that, in any future campaign I may have the opportunity of entering upon, I shall supplement dry-plate procedure with some modification of Professor Smyth's method of wet-plate manipulation.

The members of the Photographic Society are no doubt aware that Professor Smyth's recent process consists mainly in employing a small camera that can be carried about in the pocket to make Lilliputian negatives on glass, which are exposed to the lens of the camera while resting quietly in the sensitising bath, and which are subsequently enlarged at convenient and favourable opportunity to any size that may be required. The advantages which are incidental to, and, indeed, inseparable from, this mode of procedure, where such temperatures and caprices of moisture and dryness as I have endeavoured to describe are concerned, are so obvious that it would be impertinent to dwell upon them in this presence. The extreme portability of the entire series of apparatus required, the precision and certainty with which the exposure can be managed, the shortness of time, and the entire absence of all irregular

and partial drying of the film, in the first place, before the actinic influence is brought to bear upon its sensitive surface, and, in the second place, before the latent image is developed by the reducing agent, will suggest themselves on the instant. Professor Smyth works transversely upon the strips of glass prepared for the reception of microscopic objects, the negative picture so produced being just one inch square. Under this management stains are altogether unknown to him, and he can command clear brilliant pictures at all times and under all circumstances. The miniature pictures are so exquisite in detail that they do not suffer in the least when enlarged to the size of plates of the ordinary dimensions. It would be superfluous here to remark how important it is to the scientific traveller to be able to, secure, by this ingenious proceeding, an almost endless number of miniature negatives which are capable of being compactly stored in the little boxes prepared for the preservation of microscopic slides, and which can be turned to account by enlarged copying on subsequent opportunities when the exigencies of travel are past.

I should, perhaps, here add that my own inclination at present is not to work quite so small as Professor Smyth does, but to adopt as a standard for bath exposure the largest plate that proves to be consistent with easy manipulation and facility of transport.

There is, perhaps, only one other offender who requires to have his name entered in this record of photographic plagues. His name is Varnish! I have found very few samples indeed, either of amber and chloroform varnish, or of hard spirit varnish, that I could depend upon for printing under the South African sun. Nearly all prove tacky and adhesive under the heating power of the direct solar rays. Here, again, I do not doubt that much of the evil depends upon the very great difficulty of having either the sensitized paper or the printing-frames themselves absolutely dry in the atmosphere that has to be dealt with. I have lost a considerable number of plates that I should have been glad to retain, from adhesion of the paper to the varnished surface in the printing-frames. The only certain means I have found of obviating this evil has been to print only in diffused light. I adopted this practice resolutely and exclusively during my last month's sojourn in Natal; and I can but regret that I did not do so sooner.

I trust that it will now be apparent what the course of proceeding is that I incline to adopt in any future need of my own and to recommend to amateurs in warm regions, whose object in occasional and somewhat uncertain and capricious meddlings with the actual processes of photography is scientific and incidental, rather than artistic and direct.

1. I propose to use dry-plate manipulation for out-of-door work as extensively as possible, adopting some such process as the acetate of morphia plan whenever the plates can be used within a reasonably short period of their preparation, but falling back upon either Mr. England's modification of the collodio-albumen, or possibly upon Mr. Gordon's gum process, where a journey is on hand, and longer time is required. It will be remarked that, in selecting these processes, I am mainly influenced by the consideration that all materials required for them are such as can be easily kept always on hand in a fit state for use in a capricious atmosphere of high temperature and uncertain moisture.

2. I propose to prepare the collodion employed, at comparatively short intervals, in small quantities, by dissolving the dry pyroxyline in the appropriate solvents preserved in small, well-closed receptacles.

3. And, finally, I propose, wherever more sensitive plates and quicker action are required, to use chiefly small plates with a miniature camera, which allows the exposure to be made while the plate is still immersed in the sensitizing bath. It has recently occurred to me that, in all probability, the subsequent enlargements of these small negatives might be very pleasantly and satisfactorily effected upon the best forms of dry plates, either by the use of diffused solar light under a sufficient exposure, or by the adoption of Mr. Solomon's plan of employing the magnesium light.

The gentlemen of the Photographic Society of London will confer a great boon upon a large class of their amateur associates who are working in remote lands under circumstances of special "difficulty," if they will consider these propositions, and determine how far they are likely to prove sound and reliable in the conditions which I have described, and in what way it may be possible either to modify or to extend them with advantage.

## Correspondence.

## "LUX GRAPHICUS" ON THE WING.

DEAR MR. EDITOR,—I have often troubled you with some of my ideas and opinions concerning the progress and status of photography, and you have pretty often transferred the same to the columns of the PHOTOGRAPHIC NEWS, and troubled your readers in much the same manner. This time, however, I am going to tell you a secret—a family secret. They are always more curious, interesting, and important than other secrets, state secrets and Mr. McLachlan's photographic secret not excepted. But to my subject: "The Secret." Well, Dear Mr. Editor, you know that my vocations have been rather arduous for some time past, and I feel that a little relaxation from pressing cares and anxieties would be a great boon to me. You know, also, that I am a great lover of nature, almost a stickler for it to the exclusion of *prejudicial art*. And now that the spring has come and winter has fled on the wings of the field-fares and woodcocks—that's Thomas Hood's sentiment made reasonable—I fain would leave the pent-up city, where the colour of the sky can seldom be seen for the veil of yellow smoke which so constantly obscures it, and betake myself to the country, and inhale the fresh breezes of early spring; gladden my heart and eyes with a sight of the bright blue sky, the glistening snowdrops and glowing yellow crocuses, and regale my ears and soul with the rich notes of the thrush and blackbird, and the earliest song of the lark at the gates of heaven.

It is a pleasant thing to be able to shake off the mud and gloom of a winter's sojourn in a town, in the bright, fresh fields of the country, and bathe your fevered and enfeebled body in the cool airs of spring, as they come gushing down from the hills or across the rippling lake or dancing sea. I always had such a keen relish for the country at all seasons of the year, it is often a matter of wonder to me that I ever could bring my mind to the necessity of living in a town. But bread-and-butter do not grow in hedgerows, though "bread and cheese" do; still the latter will not support animal life of a higher order than grub or caterpillars. "There's the rub." The mind is, after all, the slave of the body; for the mind must bend to the requirements of the body; and as a man cannot live by gazing at a "colt's foot," and if he have no appetite for horseflesh, he is obliged to succumb to his fate, and abide in a dingy, foggy, slushy, and bewildering world of mud, bricks, and mortar, instead of revelling in the bright fields, fresh air, and gushing melodies which God created for man, and gave man senses to enjoy his glorious works.

But, Mr. Editor, I am mentally wandering among "cowslips," daisies, buttercups, and wild strawberry blossoms, and forgetting the stern necessity of confining my observations to a subject coming reasonably within the range of a class journal which you so ably conduct; but it is pardonable and advantageous to allow mind to run before matter sometimes, for the latter is more frequently inert than the former, and when the mind has gone *a-head* the body is sure to follow. Melancholy instances of that prescient themselves to our notice too frequently. For example, when a poor lady's or gentlemen's wits are gone, *lettres des cachets*, and some kind or unkind friends, send the witless body to some retreat where the wits of all the inmates are gone. I must, however, in all sober earnestness, return to my subject, or I fear you will say: "Ho is going to Hauwell." Well, perhaps I am, for I know that photography is practised at that admirable institution; and now that I have struck a professional chord, I may as well play upon it.

Lenses and cameras, like birds and flowers, reappear in spring, and, as the season advances and the sun attains a higher altitude, amateurs and professionals are quickened into a surprising activity. Renewed life is imparted to them, and the gregarious habits of man are developed in another form and somewhat in the manner that the swallows return to their old haunts. At first, a solitary scout or reconnoitering party makes his appearance, then another, and another, until a complete flock of amateur and professional photographers are abroad, seeking what food they can devour: some preferring the first green "bits of foliage" that begin to gem the woods with emeralds, others waiting till the leaf is fully out and the trees are thickly clothed in their early summer loveliness; while others prefer a more advanced state of beauty, and like to depict nature in her russet hues, when the trees "are in their yellow leaf." Some

are contented with the old-fashioned homesteads and sweet green lanes of England for their subjects; others prefer the ruined abbeys and castles of the feudal ages, with their deeply interesting associations; others choose the more mythical monuments of superstition and the dark ages, such as King Arthur's round tables, druidical circles, and remains of their rude temples of stone. Some delight in pictorializing the lakes and mountains of the north; while others are not satisfied with anything short of the sublime beauty and terrific grandeur of the Alps and Pyrenees. Truly, sir, I think it may be safely stated that photographers are lovers of nature, and, I think, they are also lovers of art. If some of them do not possess that art knowledge which is so necessary for them to pursue advantageously either branch of their profession, it is much to be regretted; but there is now no reason why they should continue in darkness any longer. I know that it requires years of study and practice to become an artist, but it does not require a very great amount of mental labour or sacrifice of time to become an artistic photographer. A little hard study of the subject as it appears in the columns of your Journal and those of your contemporaries—for I notice that they have *all* suddenly become alive to the necessity of imparting to photographers a knowledge of art principles—will soon take the scales off the eyes of a man that is blind in art, and enable him to comprehend the mysteries of lines, unity, and light and shade, and give him the power to compose his subject as readily as he could give a composing draught to an infant, and teach him to determine at a glance the light, shade, and atmospheric effects that would most harmonize with the scene to be represented. Supposing that he is master of the mechanical manipulations of photography, he has acquired half the skill of the artist; and by studying and applying the rules of composition and light and shade to his mechanical skill, he is then equal to the artist in the treatment of his subject, so far as the means he employs will or can enable him to give an art rendering of nature, fixed and immovable.

I do not profess to be a teacher, but I do think it is much more genial in spirit and becoming the dignity of a man to impart what little knowledge he has to others than to scoff at those who do not know so much. If, therefore, Mr. Editor, in the course of my peregrinations, I see an opportunity of calling your attention, and, through you, the attention of others, to any glaring defects or absurdities in the practice of our dearly beloved art, I shall not hesitate to do so; not, however, with any desire to carp and cavil at them for cavilling's sake, but with the more laudable desire of pointing them out, that they may be avoided. During the coming summer I shall have, or hope to have, many opportunities of seeing and judging, and will endeavour to keep you duly advised of what is passing before me.

My letters may come from all parts—N., E., W., and S.—so that they will, in that sense at least, harmonize with the nomenclature of your periodical. Where I may be at the date of my writing, the post-mark will reveal to you. And now I must consider my signature: much is in a name, you know. I can hardly call myself your "Special Correspondent"—that would be too much *a la Sala*; nor can I subscribe myself an "Old Photographer," for that would be taking possession of another man's property, and might lead to confusion, if not to difficulties; neither can I style myself a "Peripatetic Photographer"—though I am one—for that name sometimes appears in the columns of a contemporary; and my own name is such a long one, consisting of nearly half the letters of the alphabet. Well, I think, all things considered, I cannot do better than retain my old *nom de plume*. And with many apologies for this long round-about paper, and every expression of regard, I beg to subscribe myself your obliged and humble servant,

LUX GRAPHICUS.

March, 1868.

## GAS OR OIL LAMPS FOR THE MAGIC LANTERN.

SIR,—While endorsing the very admirable recommendation of your correspondent, Mr. Martin, relative to the non-employment of mineral oils for illumination with a magic lantern, I must dissent from him in respect to the fitness or unfitness of gas. I use gas in a lantern having a 3½-condenser and quarter-plate Voightlander portrait lens, and get exceedingly good effects with a six-foot disc. As a practical photometrist I know that there are very few towns in England in which gas is supplied of such indifferent quality as to give less than the

light of twelve sperm candles when burned in a good Argand-burner at the rate of five cubic feet per hour. I also know, from my own experiments on lamps, that the light given by a good moderator or Carcel lamp does not exceed ten to eleven candles, even when the consumption rises to the high rate of 750 to 800 grains of oil per hour, and the lamp tends to smoke. I cannot, therefore, understand why common coal gas (unless it be very common indeed, and even then the inferiority may to a large extent be compensated for by a larger consumption) can afford much less light than an oil lamp.

Your correspondent shows himself to be so well informed on the subject he writes upon, that I shall be glad to see some further observations on the lamps he considers the best to be employed, and on the comparative effects produced by them and by gas flames. For my own part I will make some trials as soon as my engagements will permit, and communicate the results, if they be of sufficient interest, through the medium of your journal.—Yours obediently,  
F. W. H.  
London, March 20th, 1868.

#### PRELIMINARY COATING OF ALBUMEN IN THE WET PROCESS.

MY DEAR SIR,—Mr. Jabez Hughes, in his excellent manual, p. 112, cautions beginners in regard to using again glass for negatives that has once been used; and few who have tried to use the same plates often will do otherwise than endorse his statement. Professor Towler, in the "Photographer's Guide," recommends that a coating of dilute albumen be given to all plates (and, of course, dried) before collodionizing; and in *Humphrey's Journal* of last year he strongly recommends it, more than once, if I remember rightly. Allow me to state my experience in the matter. A few months ago I had collected about a gross of plates, all old, and nearly all varnished, and many of them had been used several times. I boiled them in a strong solution of common soda, then washed them clean under a tap, dipped them for a short time in a dilute solution of nitric acid, washed them again very carefully, and then, while wet, coated them with a solution of albumen, 1 to 20 of boiled rain water, with a drop or two of ammonia to a pint; dried them, and put them away for use. I have now been using these plates for about six weeks, and certainly have every reason to be satisfied with them. There is no possibility by any ordinary fair means to get the film off the plate; it adheres most tenaciously, and stains-streaks and the usual consequence of using old plates are extremely rare. I am, in short, delighted with the plan, but should like much to hear something about it from others who have tried it and failed.

If albumen finds its way into the bath, of course it will soon tell. My plan, before coating with collodion, is always to clean the back of the plate and edges very carefully, and as the collodion then covers the albumen it can be very little that is exposed to the silver solution. At all events, I have not yet been able to see that my bath degenerates any the sooner because of my using these plates.

I should be very glad to learn the experience of any of your readers who have tried albuminizing their plates and have given it up. Apologising for this lengthy epistle, I remain,—Yours very truly,  
KENT.

#### SOME EXPERIENCES WITH BATHS.

DEAR SIR,—In the early part of last season I had a bath of 40 ounces which was laid aside for throwing down, only it was put in the open air, exposed to sunshine and shower. Another and another were laid aside for the same purpose, until there were six; but the sixth had bothered me a good deal at first with white markings, principally proceeding from the two corners next the head of sitter inward. These markings were half way through the film of collodion, and a little raised above the surface; they gradually wore away, however, and, after being used up, it was, like the other, laid aside and a new one commenced; but No. 7 was, if anything, worse than No. 6 in these markings; so I thought I would see what any of my old baths would do for me, and took up my 40-ounce one (the other five contained only 22 ounces of water), which did well for a day. Next day No. 2 was taken up, and did well; then No. 3, &c., with all the rest. No. 7 I have beside me, and hope it will be all the better for rest, and from having been in contact with a few collodion films.

Having tried the strength of the first bath, it was found to

contain only 24 grains to the ounce, so I strengthened it and all the rest to 35 grains with common printing silver, and wrought away with them as before, until Mr. Bovey called our attention to sugar in the printing bath, when, not expecting much more out of these old baths, and having resolved to start afresh with new ones next season, I took it into my head to treat the worst of them to  $\frac{1}{2}$  ounce of sugar, and, contrary to my expectations, it did well. Other four were treated to  $\frac{1}{2}$  an ounce each, and they also did well, and my old friend of the 40 ounces got  $1\frac{1}{2}$  ounces loaf sugar, and it did as well as any of the others, I think even better; and they were all used one after the other as before. And when, lately, our attention was called by Mr. Johnson to permanganate of potash, I thought these baths could not but be full of organic matter, so I took your advice, and got the crystals and put 16 grains into an ounce of water, dissolved them, of course, and put 3 drops into my 40-ounce friend, shook it up, but no pinkish hue; put other 3, and yet other 3, until there were 12 drops added; let it stand awhile, then filtered; it was pretty clear; but I tried 3 drops more, and no signs of the proper hue; then 9 drops were added, and at last the pink went gradually off into the brown; let it stand an hour or two, then filtered, and got a very transparent solution, which the argentometer says contains 34 grains to the ounce, but I am not so very sure about it.

The other five were treated in the same way, and with one exception, are transparent, and promise well. This one got more permanganate than the rest to bring it to the pink colour, but it positively refused to yield to the treatment, so I was obliged to let it stand awhile, and then filter; and this bath, after filtering two or three times, had a clear pinkish tinge remaining for a few days, but it has gradually changed into a fine light brown, though it has thrown down no deposit as yet. I have not had an opportunity of trying it, or any of the other 22-ounce ones, but have taken a few quarter-plate negatives with No. 1, and it promises to be as good as a new one. It behaved in the same manner as I have seen new baths behave; viz., the first plate bad, the second better, the third pretty good, but a slight deposit on the shadows, which 3 drops of strong nitric acid cleared away.

In respect to photography and disease I may say that, like our friend, D. Welch (*PHOTOGRAPHIC NEWS*, March 13th, 1868, page 130), I have wrought for four years from seven in the morning till nine, ten, and sometimes twelve at night, doing everything in connection with the requirements of a small business in a somewhat remote country place (with the exception of a little assistance in printing and mounting), and believe he is right when he says "the great temptation to over-exertion in summer, and irregularity in taking food, are greater enemies to photographers than their chemicals."—I am, dear sir, yours truly,  
W. C.

Alexandria, Dumbartonshire, Scotland, March 17th, 1868.

[Some cards subsequently produced from a negative obtained with one of the corrected baths are very bright and clean.—ED.]

#### Talk in the Studio.

PHOTOGRAPHING THE ECLIPSE OF AUGUST NEXT.—The *Athenæum* says:—"Major Tennant is going out to India to observe the total eclipse of August 18, with a special view to photography and polarization, the cost of the expedition having been sanctioned by the Secretary of State for India. Major Tennant will be accompanied by three non-commissioned officers of the Royal Engineers, well exercised in photographic manipulation; so that good pictures of all that takes place during this almost unprecedented eclipse may be anticipated."

HYPOSULPHITE OF SODA AS ANTI-CHLOR.—A correspondent of the *Chemical News* says:—"There is a large demand for hyposulphite of soda by paper makers as so-called *anti-chlor*; about 200 tons per annum are yearly consumed in photographic operations alone, while a far larger amount is used by paper-makers; hyposulphite of soda is also used by bleachers of calico fabrics. Sulphite of soda is of a more limited use, and somewhat superseded by the hyposulphite."

PHOTOGRAPHIC INVENTION.—Dr. Loewe, whose name is known to the public in connection with several secret processes for printing on silk, enlarging, &c., has a singular announce-

ment in the daily press, headed "Dr. Loewe's Toilet is made," followed by the statement that in May will appear the "First Proof of One Year of an Inventor's Existence in London, which will be a page from the Book of England, written, illustrated, composed, photographed, stereotyped, printed, and edited, by Dr. J. M. Loewe, Inventor of a Printing Process destined to make a Revolution in the Printing World."

**CARBON REPRODUCTIONS.**—Mr. J. F. Boyes, of "The Auto-type Printing and Publishing Company," writing to the *Athenæum* on the subject of Braun's carbon prints, now exhibiting, says:—"M. Braun is entitled to the highest credit for the artistic taste with which he has selected the subjects, and the care with which he has reproduced them; but the whole credit of the invention of the process is due to our fellow-countryman, Mr. J. Wilson Swan, of Newcastle, who has sold the right of working his patent in France and Belgium to M. Braun. Mr. Swan's determination to render the process in all respects perfect has been the reason why it has not been better known in this country. Having achieved this result, it may interest your readers to be informed that public attention will shortly be called to the matter, this company having just acquired Mr. Swan's patent for the process."

**CAUTION TO OPTICIANS AND PHOTOGRAPHIC DEALERS.**—We are informed that orders for lenses have been sent to more than one photographic optician, dated from Noble Street, Wood Street, stating that the goods are required for exportation, and promising cash on delivery. In one case an order was supplied, but no cash was forthcoming. In another case an invoice was delivered, with an intimation that the goods were ready on payment of the cash, but no further application for the goods followed after this condition was stated. Our commercial friends will do well to be on their guard.

**PHOTOGRAPHING CHILDREN.**—A correspondent sends us a somewhat curious advertisement copied from a Canadian paper. The advertiser is a photographer, and informs the public that "the pictures taken at this establishment are celebrated all over the world, and every where else." He announces "photographs taken in all kinds of weather," adding, however, "Bring small children on bright days only, but leave their fathers and mothers at home."

## To Correspondents.

**A READER OF THE NEWS.**—The accidental mixture of sulphate of soda with your hyposulphite does not render the latter unfit for use, as no injurious effect will be exercised upon the prints. You must take care, however, in making a fixing bath, to estimate the amount of sulphate of soda present in weighing out the hyposulphite.

**J. F. BUTLER.**—The clearing process to which you refer as practised by Mr. Osborne was not for the purpose of reducing the intensity of negatives, but rather a step in a process of increasing intensity. Its object was to remove any trace of deposit on the transparent parts of a negative after development with iron, previous to further intensifying, in order to secure very dense, clean negatives, giving perfectly black-and-white prints in reproductions of prints, plans, &c. His method consists in the application to the fixed negative of an extremely dilute solution of iodine and iodide of potassium, until any foggy deposit on the transparent parts becomes converted into iodide of silver; this is then easily dissolved off by a solution of hypo or dilute cyanide. You will find the process stated on p. 485 of our Sixth Volume, or on p. 42 of our Year-Book for 1864.

**EDUCATOR.**—In reproducing woodcuts you require to secure a perfectly clean and bright negative at the outset, free from any deposit on the shadows, either from over-exposure or fog. Any trace of such a deposit will acquire colour when treated with bichloride and a sulphide or iodide, and materially interfere with the contrasts required in the picture. You will find the gelatino-iron developer will aid you in securing bare glass in the shadows. Use, also, old collodion and an acid bath. See, also, answer above, as to a method of clearing negatives of the kind in question. One of the best modes of securing perfect opacity is as follows:—After fixing and washing and removal, if necessary, of any foggy deposit on the shadows, treat with a 5-grain solution of iodide of potassium until the film is of a uniform grey; wash, and apply a 1-grain solution of iodide of potassium until a yellowish-green tint is obtained; then wash, apply pyrogallie acid and silver in the usual manner. Almost any degree of density can be so secured.

**A. P.**—Many patents have been taken out for colouring photographs at the back, and then rendering them transparent. We do not think that any of them are now in force.

**H. S.**—The streaks on the print sent have much the appearance of being due to the glass rather than the bath. Have you satisfied yourself on this head? The negative is a little over-exposed, and the development pushed too far. Try adding a little nitric acid to the bath; expose more fully, and let us know the result.

**J. C. S.**—The lens you mention is not suitable for the production of interiors; all single lenses will give you curved marginal lines. The exaggeration of the foreground is not due to any construction of lens, but to the use of lenses of too short focus; the defect is therefore incident to all wide-angle pictures. The magnesium lamp may be successfully used for illuminating objects for photographing; but it is not suitable, we fear, for interiors of churches, as the accumulation of the smoke is an objection.

**F. W. H.**—Thanks for the interesting examples of your mode of utilizing photography, which appears very valuable for the purpose.

**W. B.**—We are not personally familiar with any one whom we can recommend. Mr. D. Rees, of 3B, Broadway, Ludgate Hill, advertises lessons on moderate terms, and we have seen some of his work in tinting cards, which is good.

**W. J. A. G.**—The PHOTOGRAPHIC NEWS is published in the Office on Friday morning at 9 o'clock. It goes to press on Thursday evening, and all copies required for post are posted during the night. We are glad to learn that you now get your copies in satisfactory time; the paper was under other business management when you received it late. We have been able during the last few months to make many business improvements.

**ENQUIRER.**—M. Petit Jean's method of silvering glass is as follows: Prepare two solutions, the first containing 3 drachms of nitrate of silver and 1 drachm of strong liquid ammonia in an ounce of water; after filtration add 16 ounces of distilled water; then add, a drop at a time, half a drachm of water containing 7 grains of tartaric. A second solution is then prepared containing twice the proportion of tartaric acid. The glass, having been thoroughly cleaned and dried, is heated to about 120 degrees, and covered with the first solution. In about ten minutes the deposit of silver commences, and is completed in about fifteen minutes more. It is then rinsed and covered in like manner with the second solution; and after about a quarter of an hour it is washed, dried, and polished.

**ANGUS.**—We shall have pleasure in inserting your communication if you append to it your own name; this is due to the gentlemen whose name you mention. Honest men, whether they are fearless and outspoken or not, do not make charges against others by name whilst they conceal their own names and shelter themselves in the dark.

**R. M. G.**—Your frequent head-aches may possibly arise from constantly inhaling the vapour of ether. The first effect of ether is stimulating; the reaction is of a depressing character, and may frequently be attended with head-ache. But remember that head-aches are amongst the most frequent symptoms of indigestion, and may arise from many causes, especially long fasting followed by hearty eating, by unsuitable food, by late and heavy suppers, by want of exercise in the fresh air, by sleeping in small ill-ventilated chambers, by excessive use of tobacco or alcoholic stimulants. See that you avoid these causes before you attribute your suffering to photography. See that the dark room is as well ventilated as you can make it; and if it be difficult to make the ventilation perfect, get your employer to aid you.

**W. C.**—Your cards have many good qualities, being generally bright and clean. Nos. 1 and 7 we like best. The chief defect consists in your use, in many cases, of too light a background. For vignettes, the background you employ is very good, but it is too light for figures fully printed out, and gives a somewhat hard effect. Your heads would gain greatly in roundness, delicacy, and vigour if they had a dark background behind them in place of the light one you employ.

**HENRY HELE.**—The book to which you refer is not recently published. It has been out many years, and was reviewed in our pages about half a dozen years ago. There has not been any new edition.

**E. H.**—We called once, but without seeing any one who could give us the information. We will ask the manufacturer to send particulars by post.

**B. M.**—The patent lens will answer as well as the triple for enlarging. 2. Of the three you mention, if you only wish to purchase one, select the triple; if you purchase two, then the other two, leaving the triple.

Several Correspondents in our next.

## PHOTOGRAPHY AND DISEASE.

THE general tendency of the evidence furnished by the experience of photographers as stated in many letters, some of which we have published, confirms the position we assumed some weeks ago, in commenting on the cases then submitted for our advice. We expressed a conviction that the practice of photography, when pursued with a prudent attention to the conditions of health, was not necessarily injurious; but that the too frequent disregard of ventilation in the dark room and studio, the careless contact with dangerous poisons, and the neglect of regularity in taking food not uncommon amongst photographers, together with the constant mental strain, were fruitful causes of debility and suffering. A letter from a gentleman in active practice as a physician, who is also an enthusiastic amateur photographer, confirms these views, and offers some valuable suggestions for the benefit of our readers. He says:—

“The question as to how far the practice of photography, under fair conditions, is prejudicial to health is not an easy one to answer without reliable and statistical evidence. I have myself been an ardent follower of the art for seventeen years, and till last year, when I was poisoned with cyanide of potassium, could trace no indisposition to its practice; but I am not disposed to regard it as altogether innocuous.

“That it might be rendered comparatively harmless I believe, by ordinary precautions, such as thorough ventilation of the dark room, and carefully protecting the hands by india-rubber gauntlets, or, as I formerly mentioned, by using horn forceps in the various operations of sensitizing paper, washing, and toning prints. No medical man can ignore the power, for good or evil, of solutions of nitrate of silver, gold, bichloride of mercury, iodine, cyanide, &c. In this instance it must be for evil, as these solutions in photographic work are all of more than average energy, and are used in quantities, and daily, far beyond the strength any prudent physician would venture to prescribe.

“We are all conscious of the penetrating odour of ether; how for hours it saturates the system, and is unpleasantly perceptible to those not accustomed to its fumes. Long after we have quitted the dark room it permeates the breath, the hair, the skin, and perspiration; and when we consider its anæsthetic properties, designedly given for therapeutic purposes, it need surprise no one if its large and continued use in ill-ventilated studios cause depression, nervous tremors, indigestion, palpitations, vertigo, and a host of other recognized but ill-understood phenomena, which culminate in the term ‘feeble health,’ so often characteristic of the professional photographer’s condition. The dark room should be ventilated, not only from above, but below, to allow the heavy fumes of ether to escape; the hands, during the periods of developing, should be frequently washed, to free them from acetic acid and other impurities; and I would

earnestly suggest to professionals to make exercise—taken in the air daily, both before and after work is over—a part of their religion; to sponge daily with cold water the whole surface of the body; to be temperate in all things; in fact, to neglect none of the usual rules of hygiene now, through the happy spread of the daily press and popular literature, so widely diffused among all classes.

“If these points are fairly considered and acted upon, I cannot think the practice of photography necessarily prejudicial, but I am not surprised that it should be otherwise when I observe in so many studios the supreme indifference to the merest precautions: hands boldly immersed through an afternoon’s toning into gold solutions; studios, one would almost think, purposely unventilated; bichloride and iodine intensifiers handled as if they were milk and water; lumps of cyanide rubbed over the hands to remove silver stains; old collodion used to clean plates, as if the smarting of the eyes, caused by it, were a pleasing pastime; and a total ignoring of all rules of cleanliness and care.

“There is also another phase of photography which I have never seen mentioned: how far the sight is effected, especially in out-door photography, by the sudden transition from the full blaze of sunshine to the comparative darkness of a tent. I have noticed some tents so ill-lighted that development seemed to me to be performed by instinct. The tent and dark room in my opinion should be sufficiently illumined by non-actinic light as to enable the operator to read ordinary print with ease, so that all strain on the eyes should be avoided. I am afraid many photographers will yet rue the day when they subjected themselves with indifference—not to say ignorance—in spite of frequent warning, to such subtle and malign influences. The professional photographer generally knows little of chemical affinities and their potency, and recklessly deals with occult and poisonous materials. It behoves him, therefore, for his own sake, to ‘tak tent,’ and secure for himself all the immunity possible from the often invisible but dangerous agencies that surround him.”

It is not from any desire to excite the alarm of any of our readers, still less to increase the anxiety of the nervous, that we have given some prominence to this question. Our aim is rather, in regard to the latter, to allay apprehension, and point out that the exercise of their profession involves no risk to health which may not be avoided by ordinary prudence and care. The anxious and worrying nature of the photographer’s duties—which, as a valued correspondent, “R. H. P.,” whose letter appears on another page, suggests, is a prolific cause of nervous debility—is not easily removed; but photographers may avoid unhealthy conditions without interfering with the efficiency of their general arrangements. Upon employers we would especially urge the importance of ventilation, for the sake of their own health as well as that of their assistants, and also as

having an important bearing upon the excellence of their productions. The best work will scarcely be produced when the system is in the exhausted and depressed condition which is the inevitable result of the continuous breathing of an atmosphere charged with the vapours of ether and some other substances used in the daily practice of photography.

#### ACTINIC LIGHT TRANSMITTED BY DIFFERENT KINDS OF GLASS.

We have been favoured by Mr. Gaffield, of Boston, United States, whose valuable experiments on the action of sunlight on glass we recently brought before our readers, with an interesting photographic print illustrating the degree of light transmitted by certain samples of glass he has examined. In this instance the experiment was intended to determine the degree of chemical action exerted by light after passing through certain samples of new glass. Fourteen examples of glass, each four inches by two, were placed side by side, duly labelled so that each should in printing register its own description on a sheet of sensitive paper, and submitted for three minutes to direct sunshine; and the print before us presents the result of the experiment, which is curious and interesting.

One half of the sheet was covered with glasses of the colours of the solar spectrum in their due order—red, orange, yellow, green, blue, indigo, violet. The nature of the colouring matter used in the respective samples is not stated, and we know that this is an important element in the power of the glass to transmit or obstruct actinism; but we assume that the glasses were selected each as pure and bright examples of its colour. The red, orange, and green have, during the exposure in question, entirely checked the transmission of actinic light, and no action whatever has taken place on the paper; whilst, curiously enough, the yellow shows a delicate tint of grey, indicating decided action of light. Blue, of course, has transmitted the most actinic light of any of the coloured samples; indigo, however, being scarcely inferior in its power of transmitting light. Violet obstructs a very large proportion of the light, the blue having transmitted at least three times as much. The other portion of the sheet is covered with samples labelled as follows: black, porcelain glass, Belgian sheet glass, Belgian sheet ground, American crystal sheet, English crown, French white plate. The black glass, as might have been anticipated, obstructs the passage of actinic light entirely. The porcelain glass, which is the American term for opal pot metal, transmits light in a degree slightly superior to the violet glass. The chemical action appears not to have been retarded in any appreciable degree by the grinding of the Belgian sheet, as whilst that glass unground transmits the light decidedly most perfectly (the paper being appreciably blacker under it than elsewhere), the same sample ground does not appear to transmit light in any degree less than the American, English, and French clear samples. This is very curious, and requires explanation, as ground glass is generally found to obstruct a very large proportion of light—in some photographic experiments as much as 60 per cent. of illuminating power being cut off when the light has passed through ground glass. English crown, American crystal sheet, and French white plate, appear to transmit actinic light in about the same degree, and decidedly more perfectly than blue glass. The Belgian sheet is, however, decidedly the most perfect sample of those tried in the illustration before us. This accords with former experience which has come under our notice regarding this glass, which is also one of those least liable to change.

Mr. Gaffield informs us that he is still at work upon his experiments with the changes effected in glass by the action of sunlight. The photographic illustration of the varied degrees of change produced by exposure during various periods, from a day to a year, are sufficiently marked for definite observation; although even in a year, in many cases,

the alteration is very slight. In the final chart of results, showing the progressive changes in a period ranging from one year to ten, a most valuable record will be secured, for which the photographic community will be deeply indebted to Mr. Gaffield, whose valuable labours will doubtless direct attention to this subject—hitherto so little considered—in a degree commensurate with its importance.

BY AN OLD PHOTOGRAPHER.

HEALTH OF PHOTOGRAPHERS—DISORDERED NITRATE BATHS, AND MODES OF RESTORING THEM—PHOTOGRAPHY WITHOUT A NITRATE BATH—REWARDS TO INVENTORS, AND SECRET PROCESSES—PRESENTATION PRINTS—THE EDINBURGH COMMITTEE ON M. SALOMON'S PRINTS—SOCIETIES.

The effect of the practice of photography upon the health of its devotees, to the discussion of which you have recently opened your columns, is a question which touches the interests of the majority of your readers, amateur or professional, very intimately. Your correspondent "Hypo(chondriac)," who thought the complaints of photographers who suffered from ill-health should be answered with good-natured railery, is doubtless one of the fortunate persons who enjoy good health. "He jests at scars who never felt a wound." But it has been my fortune to know a good many professional photographers who have persevered manfully in the discharge of onerous duties in spite of a sore amount of suffering and debility, charged, if not due, to the pursuit of photography; and I have further known zealous amateurs who have been absolutely forbidden by their medical men to apply themselves longer to their favourite pursuit. The question, it cannot be doubted, then, becomes a very important one: Is the practice of photography injurious to health? We know well that many trades have their especial diseases: the painter suffers from the action of lead salts; the grinder from the dust of the metal he polishes; the looking-glass maker from mercury; the lucifer-match maker from phosphorus; the electro-plater from cyanide; and a host of others incur, from the varied special causes involved in their daily occupations, sufferings which embitter life and bring on early decay. Is photography legitimately chargeable with any of these things? This question will, I hope, receive a conclusive answer in the course of the discussion. For my own part, I think not; and whilst I know that many photographers suffer ill-health from causes arising out of the practice of their art, I do not think that photography is an unhealthy occupation *per se*. That it is made so by ignorance, thoughtlessness, or recklessness in many cases, however, there cannot be a doubt. I have the happiness of knowing a very large number of the ablest men in every branch of our profession, and I can scarcely remember one who does not suffer seriously at times from debility; but I am inclined to believe that it is traceable, in almost every instance, not to the prudent practice of photography, but from over-taxing themselves: working anxiously as well as energetically. With the successful, the struggle to excel; with the unsuccessful, the struggle to exist; with all, the heat of the glass room, and the worries attendant on the duties there: the varied effluvia of the dark room, and the anxieties occasionally arising from pinholes, matt silver stains, fog, splitting films, dissolving films, hard varnish, bad paper, &c., operating on the nervous and irritable temperament, which is common amongst photographers—all these things are necessarily common causes of ill-health incident to, but not necessarily arising out of, the practice of photography. The discussion of the question must have the good effect of making photographers a little more careful in the handling of dangerous poisons, and a little more considerate, probably, of the ventilation of the dark room. The majority of dark rooms have anything but an agreeable atmosphere. Joey Ladle, in Dickens' last Christmas story, states that taking in the vapours of wine

"through the pores," instead of through "the convivial channel of the throttle," makes a man "muddled and melancholy." I don't think that the vapours of ether, acetic acid, cyanide, &c., taken through the pores, can, under the best of circumstances, have a very elevating effect, and it must be worth a little effort to avoid them.

From the diseases of the photographer to the disorders of his nitrate bath is an easy step. During the seventeen years the collodion process has been before the public, the nitrate bath and its troubles have been a prolific theme for discussion. Numerous have been the remedies proposed, and enthusiastic the supporters of each; but, alas! no universal panacea has yet been discovered. Addition of the oxide of silver, followed by an infinitesimal dose of nitric acid; neutralizing and sunning; boiling; freezing; precipitating as carbonate, and redissolving in nitric acid; dosing with cyanide, have each in turn been regarded as the certain cure, and each remedy doubtless has its especial value; but the nitrate bath is no more amenable to the action of a universal panacea than is the constitution of man. Within the last month or two, three novel modes of dealing with the nitrate bath have been brought before photographers. Mr. Cherrill proposes to save trouble, if not to prevent disease, by using common water in place of distilled water. Capital advice, I should think, when good distilled water cannot be had, inasmuch as the photographer will begin with common water under the conviction that it contains impurities to be eliminated, whereas he often fancies that distilled water must be pure, and that it requires neither testing nor treatment of any kind, a fancy which often involves disappointment. My friend Rejlander's remedy of keeping his bath in daylight, whenever it is out of use, seems an excellent notion. If sunning occasionally be good, to throw down organic impurities which have accumulated, the constant exposure to daylight, to throw down these impurities as fast as they accumulate, seems a very rational proceeding. Whether any other troubles will be induced by this mode of procedure remains to be ascertained by experience. The method of curing the bath of fog caused by similar accumulations, to which Mr. Johnson has called attention, seems to be one of the most simple of all the remedies; but still we shall require the record of experience before an absolute decision is made in favour of the use of a permanganate. I have heard in more than one instance that whilst fog is dismissed, pinholes are induced, by this treatment. Is this so?

Shall we ever dispense with the nitrate bath? It is clear that it can be done in the preparation of dry plates. I was glad to see Mr. Bolton's interesting article, again calling attention to the use of collodio-bromide of silver, in your columns last week. My essays with the process have not been extensive, but have convinced me of its value; and the plates prepared by it, sent out by the Liverpool Company, are wonderfully excellent. If such perfect dry plates can be prepared without the nitrate, it will be strange if we do not eventually succeed in superseding the wet process by a better and simpler process, in which all the sensitive agents are held in one vehicle like collodion. I have often wondered that a collodion containing iodide and bromide of silver, merely requiring immersion in a dilute silver solution to supply free nitrate, has never been brought into use.

The necessity or desirability of some means of rewarding inventors who may give their inventions to the public has often been discussed, but, unfortunately, no available plan has yet been devised. I was forcibly reminded of the importance of the subject the other day whilst reading the letter of Mr. Henderson in your columns, in which he stated that, incidentally to the working out of a new photographic enamel process, he had made certain other valuable discoveries, amongst which were, a permanent printing process without salts of silver, a new intensifying process, &c. The uncertainty and costliness of the patent system form a barrier to this mode of protection, and although Mr. Hender-

son would willingly publish some portions of his discovery for the benefit of photographers, he could not do so without publishing the secret of that part of which he wishes to make commercial use in order to reimburse himself for time and money expended in working it out. The necessity, under such circumstances, of preserving secret processes which might be valuable in the daily practice of the photographer is much to be deplored, but at present I do not see any remedy.

I am glad to learn that the Photographic Society is about to adopt the system of distributing presentation prints, and that plenty of volunteers were found willing to provide express subjects for distribution. Mr. H. Claudet's offer to present to the members a print from the last negative of his late father, which had fortunately escaped the fire, was a happy thought. The fact that the portrait was taken with the topaz lens in which Mr. Claudet was so especially interested gives the portrait a distinctive value, not simply as a scientific curiosity, but as a souvenir of the especial efforts of Mr. Claudet at all times in endeavouring to improve the appliances of photography. It is just the kind of illustration of his interest in photography and of his attachment to the Photographic Society which Mr. Claudet would himself have had pleasure in seeing so distributed. The three prints promised will, we doubt not, be worth more than the year's subscription to the Society.

The proceedings at the last monthly meeting of the Society were interesting. A capital paper by Dr. Mann on the difficulties of an amateur in South Africa, a paper written in an admirable spirit, occupied the chief part of the evening. At the North, the election of officers, the reading of the annual report, and a paper on the magnesium light, by Mr. Solomon, illustrated by the production of an enlargement, occupied the evening. At the South, the "Question Box" was called into requisition, and an instructive discussion of the value of permanganate of potash for rectifying disordered baths ensued.

At the Edinburgh Society, the Committee appointed to examine one of M. Adam-Salomon's prints presented its report, which is a little puzzling. It states that the print was first sponged, which removed the whole of the retouching, causing the high lights and the drawing of the eyes, mouth, and shading of the face to vanish; and that the print was then treated with turpentine, which removed the encaustic which diminished the transparency of the shadows, and showed them to be bronzed from excessive over-printing. The puzzle to which I just now referred arises from the fact that, as the first operation of sponging, before removing the encaustic, washed off the retouching, it follows that the retouching was effected after the print had been treated with encaustic paste, the colour being applied upon its waxed surface, a most difficult thing to accomplish, and presenting a rough, patchy effect when done; or, having been done on the unwaxed print, the coating of wax over the retouching, which it required turpentine to remove, was no protection to the retouching, but permitted it to be removed by a sponge and water. This circumstance is puzzling; but, be it as it may, it is not more puzzling than that the operation should have been undertaken at all. The prints exhibited at the meeting a little more than a month ago were, according to the statements of the members, very palpably touched: this being so, it ought not to have required the destruction of a beautiful picture to ascertain a fact that was so palpable as to admit of no discussion. The experiment is clearly inconclusive as to the general character of M. Salomon's pictures. To have given it any value, the operation should have been performed on one of the prints which did not appear to have been retouched, and if the treatment to which it was submitted demonstrated that it was really retouched, and had deceived the eye, then a general doubt as to the source of superior excellence in the whole might naturally have been entertained. All that has now been demonstrated is, that the colour upon a print, the re-

touching of which was easily detected by the eye, could be washed off. If M. Salomon had put this individual print forward as an untouched print, or if he had made any statement as to the general absence of retouching in his prints, or if any one had put forward such claim for him, this result would have possessed some value, as showing that some of the prints were touched; but, as it is, it demonstrates nothing. I am told that it has been urged, in defence of this act of Vandalism, that the print belonged to the Society, who purchased it for the purpose. This excuse would have been good if any one had impeached the honesty of the proceeding; but it scarcely meets the question of the good taste of a society sitting in judgment on the works of a private individual who has never challenged the opinion of such a tribunal; nor does it give a conclusive character to an inconclusive proceeding.

At the Oldham Society, in the absence of a paper, an account of M. Salomon's studio, as described in the *PHOTOGRAPHIC NEWS*, was read. Many a pleasant evening's discussion or conversation might often be secured, I fancy, if, in the absence of a paper, this course were pursued. The Liverpool Amateur Society held a successful soirée.

## PHOTOGRAPHIC PRINTING IN SILVER, THEORETICAL AND PRACTICAL.

BY W. T. BOVEY.

### REMARKS CONCERNING SENSITIZING SOLUTIONS.

The sensitizing bath employed in photographic printing has so frequently been made a subject of controversy and apparently exhaustive comment, that it would seem a bold and hopeless task to attempt further arguments with a view of throwing any additional degree of light on the matter; but the absence of any fixed principle, the altogether unscientific concoctions frequently recommended, together with the uncertainty that attends the subject, take it all in all, offer proofs louder than can be by words expressed, that the question of silver baths need further ventilating. Be it, therefore, my congenial task to enter upon the important topic, and, if possible, to submit an hitherto unpalatable mass of crude formulæ to the ordeal of criticism, until the whole can be harmonized and placed on a sure and strictly scientific basis, without which it were vain to look for certainty, for nature in her operations never works capriciously or by the rules of chance. If, in seeking a certain result, either caprice or chance is thought to interfere, let it be accepted as an axiom that ignorance is at the root of the matter. It is clear that we must try again; we have failed in detecting the ruling principle.

My dear photographic reader, I now address you on a matter which has often perplexed you, oft has set you wondering whether some imp of mischief was the presiding genius of the art you love and practice; and your bewilderments have not been removed by the thousand-and-one hints you have carefully copied from the various journals devoted to photography; and in your hour of difficulty you have been ready to cry: "Oh! for a Mentor to guide me through this labyrinth of mystification." My dear reader, be you Telemachus, I will assume the character of Mentor, and our Ulysses will be truth, as it may be applied to the subject we are discussing; so without further delay we shall at once enter on the subject of a silver bath by showing, first, the duties it has to perform; second, the varying formulæ adopted will be scrutinized, that we may discover whether or not thorough efficiency and a due economy are combined in happy union.

First, then, the part a silver bath plays in the formation of a sun picture. It will be remembered that, in my last, I pointed out the conditions observed by the paper albuminizer. The chloride salts and organic matter he adds to the paper are the precludes without which the silver bath would prove comparatively actionless and useless. Setting aside the adjuncts employed in sensitizing solutions for the present, we will indulge in the supposition

that nitrate of silver only is present in solution. Now, nitrate of silver, as I have, on more than one occasion, endeavoured to explain, is a very unstable salt, as may easily be shown by the insoluble compounds it forms when combined with most kinds of matter for which silver has an affinity, this being in accordance with a chemical law that two soluble substances must readily unite, when the resultant is an insoluble compound. The paper, by floating, is brought into immediate contact with the nitrate of silver, and the chemical operations commence at once; the chlorine leaves the base with which it was associated, and unites with the silver, forming the more sensitive medium known as chloride of silver. At the same instant a portion of the silver forms, with the albumen, another insoluble compound, recognized as an albuminate of silver, which is erroneously described as coagulated albumen. Both these compounds are sensitive to solar light, the first eminently so; the albuminate makes ample amends for being less so by the additional vigour and stability it imparts to the photograph, which is only capable of withstanding, comparatively unscathed, the action of the various chemical attacks it undergoes when a due proportion of the reduced organic body is present. Yet one more, and no less important, part has the silver bath to perform: besides satisfying the combining matter, it is imperative that it also supplies a portion of nitrate of silver to serve as food when reduction, by the action of light, begins. Summarizing the whole, the duties to be performed by the sensitizing bath may be stated as follows:—

1st. It must provide the active material to produce, by combination, the requisite amount of chloride of silver, which is the most sensitive agent present in a sensitized sheet of paper.

2nd. It has to supply the necessary amount of silver to combine readily with the albumen; otherwise the albumen is dissolved, and the print will lack brilliancy and vigour.

3rd. It must, after satiating the chemical agents, supply sufficient free silver, without which no presentable sun picture can, in silver, be formed.

With this brief summary we approach the question of formulæ such as are usually adopted by photographers, and our business will be to select from among them the one best qualified to meet the threefold conditions above enumerated.

First, then, we purpose reviewing the silver bath pure and simple, such as you, my dear Telemachus, pin your faith to. You say that your 60, 70, and 80-grain baths fulfil, in an eminent degree, every duty I have described. Granted; but cease your admiration to enquire whether either do so strictly and economically. True, an ample supply of the silver salt is present. The chloride of silver readily forms, the albumen is quickly rendered insoluble, and a wide margin is allowed for the supply of free nitrate. True; but of this last I have to complain; the margin is too wide, if you, by and by, admit my views concerning toning matters to be correct. With a well-balanced toning bath, a print obtained from an over-dose of free nitrate is too vigorous, and the delicacy that is the chief charm which makes up the exclusiveness of a photograph is lost—dead—buried in an unsightly bronzing. Here the question arises: If such things be as Mentor describes them, how on earth are we to proceed? My dear Telemachus, ere I reply to your query, let me favour you with an axiom that will, anon, prove the correctness of the new doctrine I am endeavouring to instil into your mind. Nature is a thrifty labourer; she has never yet been found using up one fraction more of matter than is absolutely necessary. Proof: look at a silver print when well produced; it is bold, yet delicate, and throughout there is no lack of vigour; yet that picture is composed of a few atoms of silver whose infinitesimal weight can scarce be estimated. Why, then, may I ask, do you employ so large an amount of the precious metallic compound, creating waste and adding to your expenses to no trifling degree? Say you reduce the proportion of nitrate of silver down to one-half: would you not supply enough and to spare? "The albumen would resent the insult by quitting the

paper," you reply; and your remark brings me to dwell for a few moments on the subject of weak baths. Probably no greater boon connected with photographic printing was ever presented than the suggestion offered by a certain "Publicola," who, I believe, was the first to propose the addition of a neutral salt as an adjunct to the silver bath. Since that time many are they who have ploughed with the heifer then provided, and numerous are the substances advised by the compounders of weak silver baths: nitrates of sodium, potassium, magnesium, and I don't know the number of others that are marshalled as the possessors of some distinct virtues when added to the silver solution. My dear Telemachus, it is all "bosh," as Brother Jonathan quaintly hath it. What would you think of the wisdom of Mentor if he were to advise you to adopt a formula stated as follows:—

Silver nitrate	...	...	...	60 grains
Rain water	...	...	...	$\frac{1}{2}$ ounce
Aqua dist.	...	...	...	$\frac{1}{2}$ "
Pump water	...	...	...	$\frac{1}{2}$ "
Snow water	...	...	...	$\frac{1}{2}$ "

You certainly would imagine that much thinking had made him foolish; yet I must ask pardon when I say that the additions often recommended as fit and proper for the office of silver-savers are marked with wisdom equal to the formula just rendered. Seriously, it matters not whether nitrate of potash, of soda, of magnesium, or any other nitrate applicable, is added to the printing bath. By abundant experiment I have satisfied myself that their operations are on the neutral side, passive, never active; and were I not pressed for space I could summon an array of argument that I think would bear me out in the assertion. As matters stand, I simply describe the part played by the neutral salt. When an albumen surface is brought into contact with water the albumen dissolves, and a dried, unglazed paper-surface only remains. In a minor degree a similar result occurs when a small portion only of silver is present in solution. If, however, the density of the solution is increased, its solvent powers are diminished. Still silver must be present, or saturation itself will not suffice to render the concentrated neutral mixture capable of preserving the albumen intact. Yet it strangely happens that the most minute quantity of silver present will exercise an influence. I have secured a really tolerable print with 5 grains of nitrate of silver to the ounce of otherwise neutral saturated solution; without the neutral salt the small amount of silver described would have been lost and useless. To cut a long story short: after a lengthened experience, I have arrived at a conclusion that no better formula for a sensitizing bath can be adopted than that given as my offering to the YEAR-BOOK, and is there stated as follows:—

Water	...	...	...	80 ounces.
Silver nitrate	...	...	...	6 "
Soda nitrate (pure)	...	...	...	3 "
Loaf sugar	...	...	...	2 drachms.

The reason why and the wherefore must, however, stand over until my next, as I am unwilling to trespass on space. And it to myself appears more prudent to cut short at once than to risk a clip of the editorial scissors that oft shows up in all its saddening disappointments that tantalizing sentence, "To be continued."

## THE MAGIC LANTERN AND PHOTOGRAPHY.

BY JAMES MARTIN.

No. 9.

As the single lantern is incapable of producing the beautiful dioramic and other effects possible with the dissolving view apparatus, I should advise my readers, if possible, to obtain the possession of the latter. It is not so complicated as might be supposed. It merely consists of two lanterns of the usual construction, mounted on a stand, and moving upon pivots in any direction, so that the disc of light from each lantern may be thrown on the screen one exactly upon

the other, so as to appear as if there was but one. This is essentially necessary, as many of the changes (such as, for instance, a summer scene to that of winter) are produced by two pictures, one in each lantern, the leading outlines of which are in every respect the same, except that one represents the scene as in summer, with foliage, running water, and green fields; the other the same trees, but bare of leaves, the water frozen, and the fields covered with snow. In this case, should the two discs of light not be correctly superposed, the effect will be the same as if, when taking a photograph, the camera has by some accident been moved during the exposure, thus producing a double outline. The obscuration and melting of the views into each other, called dissolving, and from which effect the double lantern takes its name, is effected by an apparatus fixed in front. These are of various kinds; the purpose of all is, that while the light is gradually shut off from one, that from the other is admitted by degrees. The following arrangement is one of the most simple and effective. Two pieces of sheet iron, out of each of which a semi-circular aperture has been cut, are placed before the tube of each lantern, and arranged upon slips of wood in such a manner that, by means of a small winch, the two pieces can be made to move in contrary directions at the same time, so as to gradually close one aperture entirely while the other is progressively opened in the same ratio, until it admits the passing of the whole of the light from it. There are various kinds of dissolving view apparatus: such as the binocular, which is one lantern having two nozzles, one placed above the other; the dioptric, in which the light is thrown upon glass prisms, from thence upon the screen, and lighted by the oxycalcium light (by this contrivance only one light is required); and one gas bag (of this class is the opaque lantern, which is very ingeniously contrived). Lanterns have also been made with three sets of lenses; but, taking into consideration the additional loss of light, expense, and complication of arrangement, I believe that a well-made pair of lanterns on the usual plan will be found the most generally useful. These, with a pair of good lamps, for small-sized pictures for parlour exhibitions, and an arrangement so that the hydro-oxygen light can be used for larger sizes, or when a stronger light is desirable, will leave little to be desired. A microscope should also be added, and will be found a most amusing and instructive addition. It should have two powers, a lower one for large objects and a high one for very small ones. This cannot be shown except by the hydro-oxygen light.

I have so recently given instructions as to the management of the oil lamp that I need not here repeat them. I will therefore only add that dipping the wick in vinegar, and drying it before use, is said to cause it to burn free from smoke; but the size and height of the lamp-glass chimney has much to do with the clearness and brilliancy of the light. The hydro-oxygen light is composed of two gases, which require to be mixed in certain proportions, either before or while burning. The apparatus consists of a pair of india-rubber bags, generally of a wedge-shape, each of which should be able to contain from 5 to 9 cubic feet of gas, according to the length of time of consumption and power of light required. These are furnished with stop-cocks, to which unions can be attached connected with the tubes which lead to the blowpipes. These tubes are better made of vulcanized india-rubber, which will not collapse when trod upon; about 12 feet in length each will be found sufficient; at the other ends these tubes are attached to T unions, from which short tubes convey the gases to the blowpipes, which are of various construction. I have found those answer well that are composed of two tubes, one within the other, carrying the gases on separately until within a short distance of the orifice of the blowpipe, where they become mixed, and so issue upon the heated lime cylinder. By this contrivance there is so little mixed gas that no explosion can be caused on that account. To these short tubes are affixed two small stop-cocks, by which the flow of each gas is regulated as required; before each blowpipe is a support, on which is placed the lime cylinder.

PICTORIAL EFFECT IN PHOTOGRAPHY;  
BEING LESSONS IN  
COMPOSITION AND CHIAROSCURA FOR PHOTOGRAPHERS.  
BY H. P. ROBINSON.  
CHAPTER X.

"Connection is a principle always present to the painter's mind, if he deserve that name; and by the guidance of which he considers all sets of objects, whatever may be their character or boundaries, from the most extensive prospect to the most confined wood scene; neither referring everything to the narrow limits of his canvas, nor despising what will not suit it, unless, indeed, the limits of his mind be equally narrow and contracted; for when I speak of a painter I mean an artist, not a mechanic.—*Sir Uvedale Price.*  
—"*What is Truth?*" said jesting Pilate: And would not stay for an Answer"  
—*Bacon.*

BEFORE placing figures in a landscape, the artist should first make up his mind whether the composition requires the introduction of any object to add to its completeness. If it does, do not let anything induce him to take the view without the figure, because he will be doing something that he can see could be done better with the assistance of a little more trouble; above all, he should avoid incongruity, and never, for the sake of pleasing a friend by putting him in the picture, introduce an element of discord, such as was illustrated in the Sixth Chapter.

If perfect pictorial success is to be expected, no more figures than are absolutely necessary should be introduced. One figure more would be a useless blot, and injure the effect. Care must be taken that the figures compose well in relation to themselves as well as to the landscape. In too many photographs figures are to be seen straggling over the foreground, perfect strangers to each other, to all appearance, united by no purpose whatever, except that of having their portraits taken at a great disadvantage. It, of course, may happen that in some scenes in nature figures may be found scattered over a scene in the way set forth in many photographs, and a picture of them would be quite true, and would, therefore, satisfy the desires of the matter-of-fact truth-at-any-price school, who scoff at "art-knowledge;" but it is the purpose of the artist to represent agreeable truth, or at least truths that do not irritate the eye, as false quantities jar upon the ear in verse. I am quite aware, and go as far as any in agreeing, that the real enjoyment of art is in proportion to its entire truth; but the agreeable sensations produced by pictorial representations are dependent in a very great degree on the spirit and knowledge with which that truth is rendered. Form only will not give this, neither will light and shade alone; but the union of both, although colour may be absent (but which is necessary to *perfect* beauty), suggests that truth to the mind which is one of the great functions of art. The best quality of photography is this perfect truth, this absolute rendering of light and shade and form; and a knowledge that he is debarred the charms of colour should cause the photographer to be more careful to make the most of the qualities which his art possesses, and which are beyond the reach of the painter and the sculptor. It is not open to the photographer to produce his effects by departing from the truth of nature, as has been the practice with the painter for ages; but he may use all legitimate means of presenting the story he has to tell in the most agreeable manner, and it is his imperative duty to avoid the mean, the base, and the ugly; and to aim to elevate his subject, to avoid awkward forms, and to correct the unpicturesque. Having digressed thus far in search of "what is truth," we will return from the bottom of the well to our figures.

The figures and the landscape should never be quite equal in interest or pictorial value. The one should be subordinate to the other. The picture should consist of figures with a landscape background (if they are represented in the open air), or of a landscape in which figures are introduced merely for the sake of impressing a point or adding life to the more important scene. It is true, indeed, that pictures are sometimes produced, with good effect, the converse of this, and the figures vie with

the scene in interest, but the subjects must be fine, or the success will be hazardous.

It is difficult to give general directions for doing that which must, after all, have a special consideration in each case; it would therefore be next to impossible for me to give more definite directions for the introduction of figures in landscapes than has already been stated in this and former chapters; but I may sum up the subject by saying that the figure must be *of* the subject, as well as *in* it, in order that unity may be preserved; that it must be used with a purpose, to give life to a scene, or to supply an important spot of light or dark; to give balance, or to bring other parts into subordination by being either blacker or whiter than those parts; and that what is to be avoided is the indiscriminate dragging in of figures into scenes in which they have no business, and where they do nothing but mischief. Perhaps the best lesson on this subject is to be obtained from the observation of photographs in which figures have been successfully introduced—if with the assistance of a competent teacher, all the better. For this purpose nothing could be better than a few of Blanchard's stereoscopic views, especially the series taken recently in the Isle of Wight, in which the most subtle art has "grasped the skirts of happy chance," and has converted topographical views into gems of most rare quality. Every one of these little pictures that I have seen is *made*, pictorially speaking, by the figures introduced. Not figures—mark the difference!—that he has found haphazard and photographed instantaneously, although they are chiefly so-called instantaneous views, but figures that he has met with on the spot, certainly, but has arranged with great judgment and taste according to their avocation, or in accordance with the requirements of the scene. Sailors, coastguards, children, or the more prim-looking visitors, all look what they are, and are doing that which it is their nature to do; and all this not only without the least sacrifice of artistic truth *according to law*, but with very great gain from an observation of the laws of light and shade and composition as generally received.

By way of tail-piece to this chapter and to this branch of my subject—for, with the exception of a chapter on the sky, and incidentally when I come to the consideration of chiaroscuro, I have done with landscape composition—I give a little vignette showing how simple a subject will serve to make a picture. How often do photographers travel over miles of country without finding anything they consider worthy of their attention, although, perhaps, exquisite subjects may exist at every turn of the road! The art of photography has arrived at a sufficient state of perfection, in its own way, to prevent us having any fear in acknowledging that it is not possessed of unlimited power; that the sublime cannot be reached by it; and that its power is greatest when it attempts the simplest things. But if it is not the mountain that it can represent best, what art can equal it in its representation of the molehill? And for this reason I conclude my chapters on landscape with an illustration of the class of simple subjects for the representation of which the art is pre-eminent. The illustration will show how a basket, a hamper, a stone, a log of wood, a barrel—all, or any of these—may be made valuable when a foreground presents nothing of especial interest in itself, and how, by their presence, they at once give tenderness to the distance and space to the picture.

## PHOTOGRAPHY AS AN AID TO ARCHÆOLOGY.

BY J. HENDERSON.\*

ARCHÆOLOGY has been defined as "the science of teaching history by its monuments; that is, by every monument of man which the ravages of time have spared." "By the study of the past we advance the interest of the present, and know how to make use of it for the benefit of the future."

This being the case, the reproduction by means of photography of objects of antiquity is one among the numerous applications of our art which is now receiving, as it deserves, no small share of attention.

A great deal may be urged in favour of the readiness with which copies of various objects may be made by hand, of their cheapness, durability, and the ease with which they may be multiplied; but against these may be set the absolute truthfulness which is inseparable from a photograph when taken under proper conditions; the facility with which they also may be produced; the great advantage of a stereoscopic combination of views; lastly, with regard to permanence, the carbon and allied processes, and greater care in the production of silver prints, point at least in this direction, while the simplicity of our own collodio-bromide process commends itself for yielding excellent glass transparencies, which, when encased in Canada balsam, would seem to defy the ordinary wear and tear of time.

My attention was first drawn to the subject of my paper by reading a letter in the *Times* in January last, wherein Mr. C. P. Stevens stated he had been enabled to form certain conclusions from photographs of flint implements from gravel pits at Malton, in reference to which a vexed question was raised. In a letter to me, from the Blackmoor Museum, Salisbury, that gentleman says: "I had a flint hatchet photographed yesterday; but for such objects photography is not very useful, as the yellows come out too dark."

"For matters of detail photography is admirably adapted, or for mere form. Our museum is set apart for pre-historic archaeology, and for weapons, and so on, in use by modern savages, as illustrating the collection, and photographs of rare forms of clubs, spears, ornaments, tools, weapons, &c., are useful and valuable to us. We also collect photographs of the Aborigines of various countries, and for this nothing is equal to photography, because artistic licence is impossible."

"For dolmens and other megalithic structures photography is a magnificent agent; likewise for sculptured stones of the early periods. Of course I do not now allude to any application of the art as available for other than purposes of archaeology."

"Our county archaeological societies employ photography largely in their work, and the Hampshire Society also. Some photographs of the Roman city of Silchester were taken during a recent visit of that Society to the spot."

Many important historical monuments are in inaccessible positions, which the artist has to visit hurriedly, filling up subsequently the details of his imperfect sketches. This photography does effectually on the spot. Many objects of antiquarian interest are fragmentary, and form a mere portion; the probable outline of the whole has to be deduced; others—such as cinerary urns, bones, and implements, and also Roman frescoes—when exposed after ages of interment, rapidly crumble in our atmosphere, and are lost for ever. A sketch is often attempted by a rude draughtsman, where a photograph would render invaluable aid.

The character, date, and evident use of objects, as in the foregoing instances, are frequently determined by the situation and other circumstances under which they are found, and here our art is of great use.

I have, on a former occasion, referred to "architectural photography," and now, in relation to the archaeological part of the subject, I may add that, although the architect will learn more by making a careful sketch of an old building, yet you will very seldom find two sketches of the same sub-

ject which agree perfectly, while the time and skill necessary to copy the endless intricacies of detail (say) in a Gothic building, would be better spent in taking a few photographs of the same. Photographs show the difference in the courses of masonry, which often determine relative dates. They also show the juncture of work of different periods and later insertions; and in connection with this subject I may urge the desirability of photographing churches, &c., before and after restoration.

As illustrating and adding force to what I have said, I may remind you of what has been done by our own Government, by public and other bodies, and by individuals who have employed photography for the purposes I have named.

By command of Her Majesty, photo-zincography has been employed to reproduce in facsimile a selection of the national MSS. of England, from the Conquest to the reign of Queen Anne. Thus far, 230 have been published, to which the Domesday Book must be added. About 80 MSS. of Scotland are already in the hands of the public, and more of that country, and also Ireland, are to follow. By the same process some municipal and other archives have likewise been copied.

The Ordnance Survey of Stonehenge and of Turnaschau (I. of Lewis) is accompanied with illustrative photographs.

In a communication received after the rest of my paper was written, Mr. C. J. Stevens, in speaking of the value of the Ordnance photographs of Stonehenge, refers to his remarks upon them in the *Athenæum*, also to Mr. Parke's photographic illustrations of the "Antiquities of Wells," and after enumerating photographs of Celtic and other relics (including those of the Swiss lake dwellings), he proceeds to say: "The stone axe from Malton, and the beads from whence it was derived, are chiefly known to archaeologists by the published photographs of them;" and concludes thus: "An artist is not necessarily an archaeologist, and he may slur over or misrepresent some trifling (to him) detail. I have a photograph of a church, with the village, cross, &c.; upon the latter, even the chalk scribbings of boys are shown. No artist would have taken this; but in a strange country and with all to learn about the antiquities and the people, such minuteness is invaluable."\*

The India Office has published an important work with photographic illustrations: "The Textile Manufactures and Costumes of the People of India"; and the Indian Government has recently directed the whole of the ancient buildings of India to be photographed.

The Ordnance Survey of Jerusalem has been the means of many valuable photographs being taken there, and the Hon. Secretary of the Palestine Exploration Fund also says: "We have already materials for almost an entirely complete and accurate map of the country, and photographs of more than 300 spots and objects, large numbers of which have never before been taken."

There are catalogues of photographs of about 10,000 objects of antiquarian interest in South Kensington Museum, not to mention the numerous photographs taken of loan and other collections, and also at the British Museum.

While making a passing allusion to the use made of photography by our English and other Antiquarian Societies, I may mention that the Archaeological Society of Rome have proposed to photograph any antiquarian discoveries they make, and send copies to the Society of Antiquaries in London for publication. One account says: "Mr. J. H. Parker is proceeding with a collection of photographs of the ancient monuments of Rome and the Campagna, with a view to facilitate the researches of archaeological students, and demonstrate the successive styles of Roman construction during the periods of the kings, the republic, and the empire." At that date about 500 photographs had been so taken.

The mysterious remains of Egypt have attracted the attention of photographers from the first. Frith was early in the field, and was followed by Bedford, who also illustrated

\* Read before the Liverpool Amateur Photographic Association, March 31.

\* I am indebted to Mr. Stevens for the permission to use his remarks, which were not intended for publication.

Palestine, Greece, &c. The Vicomte de Rougé, in his mission to Egypt in 1863-4, produced six volumes of hand copies of inscriptions and 220 photographs.

Professor Piazzzi Smyth lately took 166 photographs at the Pyramids (many for the lantern) and 50 stereo views. Most of them were taken "solely with a view to procuring aids to scientific enquiry." They were produced on glass slips, 3 inches by 1 inch, exposed while in the bath, and they include eleven views in the interior of the Great Pyramid by magnesium light. He prefers stereo views taken with two cameras, and very justly urges the taking of distant objects with the cameras placed widely apart. This, I think, we might often do with advantage, using one stereo camera, first taking one half and then moving the camera and re-focussing for the second half.

In this connection I ought to mention the labours of Thompson among the ruins of Cambodia; Fergusson and Hopley in Indian architecture; and Svaboda at the Cave of Elephanta, likewise in Mesopotamia and on the sites of the Seven Churches of Asia; Hellsby has illustrated some of the antiquities of South America; and a new work on Central America by Squier is, I believe, to be illustrated by 3,000 photographs, and any one acquainted with the elaborated monuments of that country will admit that by no other means could fair representations be given.

It would be tedious to enumerate the volumes bearing on antiquities which photography has illustrated, either directly by silver or other prints, or as furnishing a ground-work to the wood-cutter. In "Sinai Photographed, or Contemporary Records of Israel in the Wilderness," Lord Lyndhurst suggested the application of photography "as the only way so to certify their copies of the inscriptions as to silence cavil." Noel Humphrey's interesting work on the "History of the Art of Writing" is cleverly illustrated by photography.

Our art-science has been employed, to some extent, in illustration of old coins and medals, also in copying old mosaic pavements on a reduced scale. Some time since Mr. Rejlander turned his attention to the ancient brasses for which our country is so famous; and, by super-imposing rubbings on sensitized paper, obtained copies same size as the originals. I am of opinion that negatives of the rubbings, reduced to a known scale, would yield equally useful and more convenient prints.

Of the numerous works of antiquarian interest I will only mention "The Ruins of Pompeii"; but I may mention that, as its counterpart in this country, "Uriconium," a photograph previously taken, was useful in enabling 120 columns of a hypocaust to be restored after they had been wantonly overthrown.

Some of the details at Iona, and upwards of a hundred photographs at Melrose, have been taken, the latter embracing everything of constructive or ornamental interest; and it is somewhat in this spirit that I would urge the copying, by photographic means, wherever practicable, of such works of antiquity as remain to our own day, as well for the purpose of study as for transmission, if possible (either in the form of negatives or prints), to posterity, to whom the originals may be partially or entirely lost.

The portico of the Temple of Drudeia, on the Nile, was added by Tiberius, but against this recent acquisition may be set the fact that Egyptian monuments known to exist in the fourteenth century are now no more. Of some treasures of antiquity now lost, only rude representations have come down to us; for example, on the arch of Titus at Rome we have some of the sacred trophies from the Jewish Temple, and, in this country, drawings of the famed shrine of St. Thomas of Canterbury, only exist on portions of an undestroyed window, and in a partly burnt manuscript.

The idea I have suggested may appear speculative, if not visionary; but who shall say whether our art-science may not be the means of much more being known hereafter of men and things as they existed in the nineteenth century than could have been had photography been unknown?

Let me include in the words from the "Essays of Elia":—

"Antiquity! thou wondrous charm, what art thou? that being nothing, art everything! When thou wert, thou wert not antiquity; then thou wert nothing, but hadst a remoter antiquity, as thou calledst it, to look back to with blind veneration, thou thyself being to thyself flat, *jeune*, modern! What mystery lurks in this retroversion? or what half Januses are we that cannot look forward with the same idolatry with which we for ever revert! The mighty future is as nothing, being everything! The past is everything, being nothing!"

## RESEARCHES ON DRY PLATES.

BY M. CAREY LEA.\*

### NEW PROCESSES.

I SHALL now proceed to describe the new processes referred to at the commencement of this paper.

Several years ago I described a method of developing both positives and negatives with the aid of a lead-salt. I did not claim to have discovered that lead-salts impart additional activity to gallic acid, but I showed how this principle could be advantageously used. Gallic acid precipitates acetate of lead, and in the earlier experiments this muddy mixture was employed. I showed that clear solutions could be got with acetate of lead by adding a sufficient quantity of acetic acid beforehand, which prevented precipitation; and that with nitrate of lead no precipitation tended to form, even without the need of employing acetic acid. I showed that the effect of acetate of lead was so extraordinary as to multiply the power of the gallic acid fifty-fold, so that, instead of using gallic acid in the proportion of 5 grains to the ounce, it might be reduced, with the aid of acetate of lead, even to 1-12th of a grain to the ounce; and that in the proportion of 1-6th of a grain to the ounce it was a very powerful developer. This method was not only extensively used, but, I am sorry to say, was extensively borrowed, with trivial alterations and somewhat scanty acknowledgments. In Paris it was made the foundation of a secret process. Vials containing the two solutions were sold at the rather extravagant price of thirty-eight francs. Some of the contents having been forwarded to Dr. Schnauss for analysis, his examination resulted in showing that the materials used were precisely those which I had indicated.

I have applied this principle in an entirely new direction, to the preparation of dry plates, instead of to developments, and with excellent results. A plate is coated with collodion-bromide, and is thrown, as soon as set, into a bath of acetate of lead, acetic acid, and gallic acid. It is then simply dried, without any other treatment, and so gives an excellent dry plate, very sensitive, and giving satisfactory negatives. The details are as follows:—

In 16 ounces of ordinary acetic acid (not the glacial) dissolve one drachm of acetate of lead. Prepare also a 60 grain solution of gallic acid in alcohol. Both will need filtering; both will keep a long time, probably indefinitely.

To make a bath suitable for a 4-4 plate, take 1 ounce of the lead solution, 1-4th of an ounce of the gallic acid solution, and 6 ounces of water. Add the lead solution first. No precipitate or troubling will take place (unless, perhaps, in some water containing a large proportion of sulphates, in which case, either use distilled water, or filter and add a little more lead solution), and the bath is ready at once. It is better to prepare three such baths, for the plates are made so rapidly that, otherwise, delay will occur for want of a bath to put the plates in.

The collodion is the same as that before recommended, viz., 8 grains bromide of cadmium, 2 grains bromide of ammonium, but with 7 grains pyroxyline to the ½ ounce of alcohol and ½ ounce of ether. Sensitize with 16 grains of finely pulverized nitrate of silver to the ounce.

The quality of the pyroxyline to be used is of very great

\* Continued from p. 152.

importance, as in most dry processes. Common negative cotton is not suitable, but a powdery pyroxyline of the intense sort is necessary. That sold as "Helion No. 1" gives very good results. It is curious that the intense pyroxyline which give the least sensibility with wet plates give the greatest with the dry. Of course, the collodion will be better after standing a while.

To obtain a smooth plate with collodio-bromide requires more care than with plain collodion. Pour on plenty, commencing far up the plate. Get it quickly to the upper corners, and then bring it down as squarely as possible; avoid the necessity, as far as practicable, of bringing it down first on one side and then on the other, and get it down as straightly as possible. To do this the supply must be abundant. Pouring off requires especial care, or else an uneven band will be formed across the upper end of the plate. To avoid this, raise the further end of the plate in pouring off very slowly and regularly; give the plate a wide, slow, rocking motion. Attention to this will be found important.

I should have said that the plate, before collodionizing, must have an edging of india-rubber dissolved in benzole.

The variation upon this process consists simply in washing the plate after collodionizing, and before plunging it into the bath. This makes a great difference in the plate. Treated in this way, and with a moderate exposure, clear, bright negatives are got, resembling very closely those afforded by wet plates, and showing as positives by reflected light. The deeper shadows are represented by clear glass; there is a complete absence of veiling, and brilliant pictures are easily got; but the great sensitiveness of the plate is materially diminished, the exposure is prolonged (must be from one-half more to double), and the details in the shadows are not so well preserved. I prefer, therefore, as a general thing, the first-described system, in which the plates are plunged into the lead bath as soon as set, and without preliminary washing. And I would call attention to the fact that, so far as I am aware, no one has previously proposed any method in which plates prepared in any other way, either with collodio-bromide or in any other form of the collodion process, can be sensitized without a previous washing. This new mode of operating has the double advantage of saving time and trouble, and giving a better result. It seems especially applicable for the preparation of dry plates in travelling, as the two greatest difficulties are done away with—the nitrate bath and the washing—for water with which to wash the plates made on a journey is apt to be scarce in quantity and of extremely doubtful quality.

#### ANOTHER MODIFICATION.

An interesting modification of this process is one in which the lead and gallic acid are introduced into the collodion. For this purpose, add powdered acetate of lead to acetic acid in as large quantity as it will take up. Add 5 drops of this and 15 of a 60-grain alcoholic solution of gallic acid in alcohol to each ounce of collodion, using for this purpose the same collodion as above described, likewise sensitized with 16 grains of nitrate of silver to the ounce; after standing, decant the clear portion into a measuring-glass, and add, first the lead solution, stirring well up; and then the gallic acid. Collodionize, using the same precautions as before described.

These plates, after collodionizing and setting, will simply need washing for about five minutes under the tap, and are ready for use as soon as dry. The negatives obtained resemble in all respects those obtained by that modification of the previous described process in which no washing is used. They are very sensitive, and give soft pictures. All these plates are intended for alkaline development, respecting the proper application of which a few words should be said.

#### ALKALINE DEVELOPMENT.

The form of alkaline development which I have found most suited to these plates is as follows:—

1. Carbonate of ammonia in 20-grain solution.
  2. Pyrogallie acid, 300 grains dissolved in 5 ounces of alcohol.
  3. Bromide of potassium, 2 drachms in 5 ounces of water.
- I prefer to develop in pans, and take:—
- |                       |     |     |     |     |                      |
|-----------------------|-----|-----|-----|-----|----------------------|
| Water                 | ... | ... | ... | ... | 6 ounces             |
| No. 1                 | ... | ... | ... | ... | $\frac{1}{2}$ ounce  |
| Nos. 2 and 3, each... | ... | ... | ... | ... | $\frac{1}{2}$ drachm |

This quantity, placed in a 7 by 9 porcelain pan, conveniently develops a 6 $\frac{1}{2}$  by 8 $\frac{1}{2}$  plate. The plate, after previous wetting, is left to itself in the solution for about half an hour. The dose of carbonate of ammonia is then trebled, and intensity soon comes; if it does not, the plate is left in until it does. I do not recommend washing off and using silver and pyro, but finishing entirely with the alkaline treatment.

#### MANAGEMENT OF COLLODION.

It is better, after adding the silver, to shake violently, and repeat this once or twice in an hour or two, then let repose for twelve to twenty-four hours. In this way no filtering is necessary.

After finishing a set of plates, add to the residue of the collodio-bromide 1, 2, 3 or more ounces of the bromized collodion, enough to more than saturate all the excess of silver (half as much fresh as what remains is plenty; more will do no harm); mark the quantity on the bottle, so that, in adding the next lot of nitrate of silver, it may be taken into account. Thus the operator may go on indefinitely, as Mr. Mawdsley has pointed out.

It must be well understood that even after this addition, the collodion, though less sensitive, is still very much so, and must be carefully preserved from light, and should be kept in a cool place.

#### SELF-DEVELOPING PLATES.

I published lately a description of a method of preparing plates which would spontaneously develop themselves in the dark slide, given rather as a matter of curiosity, however, than of decided utility. Continuing, from time to time, my experiments with it, I obtained very irregular results, especially in respect of fogging. By continued investigation, however, I have succeeded in ascertaining the sources of these irregularities, and in getting rid of most of them. Of the fogging, which was the most serious trouble, I got rid entirely. I give here the results which I found.

1. A picture which will develop itself entirely and not need redevelopment will require a strong, bright camera-image, such as is only got with short-focus lenses and with large diaphragms. The exposure must be as long as for a common tannin plate.

2. But, with shorter exposure, a visible image can be got, which redevelops easily to any strength desired.

3. The images lose, to an unusual extent, in the fixing, and therefore allowance must be made for it, or else the pictures will need to be returned to the developing bath for a few moments after fixing and washing.

4. Owing to the glycerine used, care must be exercised to rock the plate, though, thoroughly, otherwise crapy lines will result.

5. The same cause, the glycerine in the collodion, diminishes the adhesion of the films to the glass, causing them to slip. This is avoided by using a substratum of albumen, by the aid of which the plates will bear rough handling and rough washing with impunity.

6. *Fogging*.—This trouble showed itself in a very perplexing way. Sometimes films prepared with a large (comparative) excess of nitrate of silver showed no trace of fogging, whilst at others this result was precisely reversed. It was finally ascertained that the fogging depended wholly upon the condition of the collodion; after fixing these conditions with certainty, no difficulty was found in preparing films so entirely free from all tendency to fog that the plates, after removing from the slide, could be left in plate-boxes for weeks without undergoing any change.

As above explained, collodion, after being silvered, remains for a variable time in a condition that it gives blue and transparent films, and then changes and gives creamy opaque ones. Now, whilst the latter condition is the best for the preparation of plates intended to be used dry, the former—the bluish condition—is absolutely essential for plates to be used wet. This distinction is one of no small importance, and, by attending to it, all danger of fogging with these self-developing plates is avoided.

The best method of operating is to use the above-described collodion, adding to it  $1\frac{1}{2}$  grains of nitrate of silver to the ounce. Shake long and well, and set aside for from one to four or five hours. The colder the temperature the longer will the collodion remain in the blue condition, and the longer time may be allowed for settling. Decant all but the bottom portion into a measuring-glass, and add to each fluid-ounce:—

Alcoholic solution of gallic acid (60 grains to the ounce) ... 10 minims  
Pure concentrated glycerine ... 10 drops

If preferred to drop the gallic solution, 15 drops may be employed instead of 10 minims. As the glycerine is too thick to measure in a minim glass, it needs to be dropped. The gallic solution must be filtered perfectly clean. Stir up thoroughly with a glass-rod, remove all bubbles with a piece of paper, and collodionize the plate.

From what has been said in the previous part of this paper, it is evident that the collodio-bromide mixture used for these plates must be fresh. In working with dry plates we may save the residue by adding a certain quantity of bromized collodion, enough to bring the alkaline bromide into large excess, and thus these portions may be set aside to be re-sensitized when wanted. But this cannot be done with the self-developing plates, because they must have sensitive collodion which has never passed into the creamy state. Collodion, therefore, for the self-developing plates must be mixed, shortly before it is wanted, of entirely fresh materials, and in a clean bottle. Such portions as may remain over must be rejected, whether or not the gallic acid has been added.

I have been able further to improve upon this process by the agency mentioned already in connection with the regular dry process here described. I allude to effects produced by a lead salt. If a strong solution of acetate of lead in acetic acid be made, and 4 or 5 drops of this be added to the sensitized collodion just before use, and immediately previous to the addition of the gallic acid as here described, a better plate is obtained than where gallic acid is used alone. It is more sensitive, gives a bolder picture, and does not seem more disposed to fog if the precaution be used of using the blue film.

Although this process is a curious and interesting one, and quite novel, it is not to be compared, I think, with those described before it. The exposure is longer, and the films require more care to keep them on the plate. It is, however, certainly remarkable that a collodion film can be put into condition to go on slowly developing itself spontaneously, and yet show no disposition to fog.

#### CONCLUDING REMARKS.

It has been the object of the writer in making these researches to find a process, which whilst giving thoroughly satisfactory results, should dispense with the complicated manipulations which render dry processes uninviting. He believes that the processes described in this third part will be found to have accomplished this result, especially that one in which a plate is simply collodionized, then as soon as set, plunged into the lead bath. It is believed that no one before has proposed to apply a sensitizer to a collodion plate containing pure nitrate of silver, without previous washing, and that it is here for the first time shown that this mode of operating gives a more sensitive plate with less work than the ordinary methods. By the mode of proceeding here directed this sensitizing bath is not rendered

troubled or cloudy by the immersion of the washed plate, but remains perfectly clear.

Of the various methods which he has described the writer is disposed to recommend this one, applying the modification of washing before using the lead bath, where a bright clean plate with clean glass in the deep shadows, and plenty of contrast is desired; for general use, however, omitting the washing. By preparing one or two washed plates in each set, and making a W in the corner with a diamond, or even simply scratching a cross with a broken file, the operator will have plates suitable for all needs, the washed plates being reserved for wide views well illuminated throughout, and in which it is desirable to preserve and even to increase the contrasts which actually exist, whilst for all other uses the unwashed plates will have the preference.

## Proceedings of Societies.

### OLDHAM PHOTOGRAPHIC SOCIETY.

THE Ordinary Meeting of the above Society was held on Thursday, the 26th inst, the President, Mr. JOHN GREEN, in the chair.

After the minutes of the previous meeting had been read, Mr. James Hall was duly elected a member.

Messrs. WOLSTENHULME then handed round a couple of negatives, one being marked with small spots and streaks, the other being quite good, and all that could be expected. Messrs. Wolstenhulme stated that they were both from the same bath, taken immediately after one another, which caused a lengthy discussion.

Messrs. WHITEHEAD and HEATON then exhibited a tent made expressly for out-door work.

Mr. HEATON stated that the tent he considered to be the most convenient one he ever used, and he had worked in several. It was what he might call a modification of Leak's, it being constructed for holding the bath, legs, and everything requisite, and could be placed under a railway seat when travelling. It was very much admired, and considered to be as perfect a tent as any photographer could wish. Mr. Heaton then read his paper on Out-door Photography. (This paper, owing to the pressure in our space, is unavoidably left over until our next).

A vote of thanks was passed to Mr J. Selwape, of Rhodes, for some very beautiful prints for the portfolio; also to Mr. Heaton for his paper, which brought the meeting to a close.

### LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE Ordinary Monthly Meeting of this Association was held on Tuesday evening, the 31st ult., the President, the Rev. G. BANNER, in the chair.

The minutes of the two previous meetings having been read,

Mr. GREEN said he wished to call attention to one of the minutes of the January meeting, referring to the picture presented to the Hon. Secretary, which had not been fully reported. The following is the inscription upon the picture, and will explain matters fully:—"This photograph, being the largest hitherto taken by the collodio-bromide process, is presented by the Liverpool Amateur Photographic Association to their Secretary, Mr. W. Bolton, to whom photographers are mainly indebted for the discovery of the method of producing a photograph without a bath; and in testimony of his zeal in promoting the objects of the Association."

Mr. HENDERSON was then called upon to read his paper entitled "Photography as an Aid to the Study of Archaeology," (see p. 163) at the conclusion of which a number of very excellent photographs illustrating the paper were passed round, and also several volumes of photo-zincographic copies of old manuscripts, &c., including the Domesday Book for Lancashire and Cheshire.

A vote of thanks having been accorded to Mr. Henderson,

The Rev. T. BANNER said, that the subject Mr. Henderson had chosen was one which might be enlarged upon to almost any extent. He quite agreed with Mr. Henderson as to the superiority of photographs over drawings. He himself had made a sketch of a Norman gateway, near Oxford, which had occupied him two days, and which might have been very

much better done in two minutes by photography. He also thought that no faith was to be placed in drawings; he had compared an engraving of Sardinia, which was in his possession, with one of Svaboda's pictures of the same subject, but could trace no resemblance between the two. He concluded by thanking Mr. Henderson for the trouble he had taken in collecting matter for his paper.

Mr. HENDERSON said that whatever trouble he had taken had been a pleasure to him; for he had been led into very pleasant correspondence and instructive reading.

Mr. NEWTON made some remarks bearing upon the use of photography in copying old pictures and other works of art, the series just introduced showing the complete success which might be attained.

Mr. FORREST then read a paper on "The Satchel Camera," and exhibited his camera and stand, the latter of which received the greater share of attention. It is constructed upon the tube principle, and packs up in the form of an umbrella.

Mr. FORREST pointed out that his dark slides were painted yellow inside, and this he stated he had found to completely stop blurring.

Some discussion took place on this point, the unanimous opinion being, that painting the back of the plate is the only way of effectually staying the evil.

A vote of thanks was passed to Mr. Forrest, who had gone to a great deal of trouble and expense in obtaining from London one of Moucheven's enlarging cameras, which, unfortunately, was not put to any practical use.

Mr. HUGHES passed round two negatives on plates prepared by the Liverpool Dry Plate Company, which had been developed nearly three months after exposure, which, though taken during December, possessed so much delicacy and half-tone as to rival any process, wet or dry.

The Rev. T. B. BANNER said he had been using some of the same plates for portraits. He had exposed one plate one minute, and obtained a beautiful negative, and another exposed two minutes was ruined by over-exposure. The plates were not new, but were some that he bought last year.

Mr. HENDERSON stated that he had seen a collection of photographs taken before the gold toning had come into use, and though the majority of the prints were quite faded, some still remained perfect, showing that it is possible to prevent even a sulphur-toned print from fading.

Mr. Green's prize photograph was awarded to Mr. W. H. Wilson.

Mr. HUGHES and Mr. HIGGIN exhibited some enlargements from microscopic objects, which were considered very good indeed.

The meeting adjourned rather later than usual.

## Correspondence.

### PHOTOGRAPHY AND DISEASE.

DEAR SIR,—I feel grateful for the opportunity you have given your readers and correspondents to discuss in your columns the question, "Is photography inimical to health?" And, as we may expect your own judicious and careful summing up on the facts elicited, I trust a true answer may be obtained.

I quite agree with Mr. Hall, in your last number, that a perfect solution could best be obtained by comparison of the general photographic experience; but then nothing short of a special census would avail, and of this I fear there is no hope. For my own part, I am inclined to think that the worry and tension of mind usually inseparable from professional work have more to do with the deficiency of health often found amongst photographers than the effluvia of the dark-room. Add to this the uncertain hours and irregular strain of work and variable times for meals, and you have a condition of things that in any other calling would be considered almost unbearable.

Looking round (mentally) on my acquaintances in the profession, I do not think I could point to one who is "the picture of health," as I might amongst (say) the grocers of my town, and I think it is more this below-par condition that is prevalent than decided ill health, though that is not very rare, I believe. Men of science, and those engaged in any brain work,

do not, I am aware, stand a chance of keeping up the physique like him "who feeds fat oxen," a fact which proves that nature's golden mean of mental and bodily labour cannot be transgressed without loss; but in most other walks of life there are more numerous times and hours of relaxation than, as a rule, fall to the photographer's lot; and hence the mind and body, from running incessantly in one groove, show signs of wear and tear at length. The public, too, are scarcely so considerate as might be desired, and often press for sittings at holiday times (when "decked in all their best" no additional time or trouble is needed for a separate dressing), and the good-natured photographer seldom holds out against the importunities of his customers supported by the claims of his purse. Perhaps, also, the unfair competition, which often has to be met by extra diligence and unswerving care, adds the pressure from other quarters; but this, fortunately, is waning, and for those who have weathered both the storms of prosperity and adversity there seems a prospect of something like halcyon days.

Probably one result—and not the least—of the various communications you have received on this topic, will be, that photographers will, as much as possible, avoid all injurious contact with their chemicals, and believe in the wisdom of giving that useful servant, the body, its due, by air, exercise, and rest—things that in these "express" days are apt to be forgotten.—I am, dear sir, yours truly,  
R. H. P.

PS.—I have just been informed that one of the cleverest photographers in Clifton (Mr. Beattie) has had to resign his business from ill-health, it is thought, photographically induced.

## Talk in the Studio.

THE SCIENCE OF THE SUNBEAM.—Mr. Jabez Hughes recently delivered the closing lecture of the season at the Isle of Wight Philosophical Society, his subject being the Science of the Sunbeam. Our space precludes the printing here of even an analysis of a most eloquent lecture, which was, we understand, one of the most successful and brilliant delivered during the session.

PHOTOGRAPHIC SOUVENIR OF TASMANIA.—In the midst of the public demonstrations in honour of the visit of H.R.H. Prince Alfred, Duke of Devonshire, to Tasmania, photography played its part. At a farewell banquet the Prince was presented with an album of photographs of Tasmanian scenery, which had been under the directions of the Preparation Committee, for presentation to H.R.H. the Duke of Edinburgh, from the colonists, as a memorial of his visit to Tasmania in H.M.S. *Galatea*. The album was a most beautiful and costly volume of improved size, bound in crimson morocco, gilt, and ornamented in an elaborate and tasteful manner. It contains 83 photographs illustrative of the scenery of Tasmania, 48 portraits of children born in the colony, and 9 plates immediately connected with the Prince's visit. The title-page was drawn by Mr. Alfred Randall, and illustrated by Mr. W. C. Piquenit. H.R.H. was pleased to request that the Preparation Committee would furnish him with duplicate copies of all the pictures for the illustration of a work which H.R.H. is preparing in connection with his visit to the Australasian Colonies.

A HINT AS TO LABELLING NEGATIVES.—A correspondent sends us the following useful hints:—"In putting away my negatives, at the back and at one end of each a slip of albuminized paper, about one-third of an inch wide, is stuck on; upon this the No. of negative, and S. or R., according to which paper suits the quality of negative (Saxe or Rive), and D. if (as some subjects, I find, need) deeper printing than ordinary is required. By this means, on taking a negative out of the box to print from, it tells its own tale, and produces the same results as the first proofs. I was led to do this from the fact I had had brought under my notice, that after the first order sent to a photographer, the prints were rarely up to the mark in subsequent orders."

SOUTH LONDON EXHIBITION MEETING.—Members are reminded that the meeting of the Society to be held on Thursday evening, the 9th instant, is to be devoted to examination of, and conversation on, photographs, which members are invited to contribute for the occasion.

## To Correspondents.

**TO AGENTS AND ADVERTISERS.**—Next Friday being Good Friday, the PHOTOGRAPHIC NEWS will be published on Thursday, April 9th. Advertisers should send in their Announcements not later than Wednesday, the 8th.

**EDUCATOR.**—The causes of collodion giving a thin transparent film may be various: deficiency of pyroxyline, deficiency of iodide, or lack of porosity or permeability in the film will cause it. The latter cause may be the result of the use of a pyroxyline giving a horny, repellent film, or the use of anhydrous solvents; if the latter, the addition of a drop or two of distilled water to each ounce of collodion will remove the defect; if the former, time will be the best cure. If deficiency of iodide is the cause, it may be remedied by the addition of about half a grain of iodide of cadmium to each ounce; but this is rarely required. The addition of a little more pyroxyline is often of service in securing a creamy film and a vigorous negative. About a grain of good pyroxyline to each ounce of collodion will often effect an improvement.

**J. H.**—We recommend common sheet glass as most suitable for a studio, being cheapest and least liable to change under the action of light. If a small space is to be covered, a 15-ounce glass will be sufficient; if a larger space, a stronger glass (say 21-ounce) is better.

**Z. H. A.**—The proportion of acetate of soda you use is very excessive. The usual formula is 30 grains to 1 grain of chloride of gold; you are using 600 grains. You also use the bath too weak; 10 ounces of water to each grain of chloride of gold will give a very dilute bath; 5 ounces of water are sufficient. The tendency of excess of acetate of soda will be to prevent the keeping of the bath, causing it to become gradually inert, and tone slowly and imperfectly.

**F. F.**—A ridge-roof room, with the side and roof facing north, glazed, and the other side opaque, will be best. The space you have at your disposal must determine the proportions. Secure as much length as you conveniently can.

**J. C. G.**—We cannot recommend the instruments of any maker by name here. If you will send us a list (you may find some in our advertising columns), distinguishing each by a number, we can advise you as to which is most suitable for your wants.

**T. S. (Biggleswade).**—Water purified by the addition of a little nitrate of silver and sunning is suitable for making silver baths, but not for other photographic purposes. It would not be suitable, for instance, for making a toning bath, because the nitrate of silver remaining in solution would decompose the bath and throw down the gold. The yellow precipitate you describe is probably oxide of gold.

**M. CAGE.**—In the formula to which you refer, where acetic acid simply is mentioned, glacial acetic acid, which is that commonly used in photography, is meant. It is only when a deviation from the usual standard is intended that the qualification need be stated; hence, when the weaker acid is intended, Beaumont's is mentioned. It is about one-third of the strength of the glacial acid. 2. The solution or paste of bees'-wax is used after the print is mounted on ordinary cardboard. Care must, of course, be taken to avoid touching the margin; this is easily done. Mr. Blanchard has given up the commercial application of collodion to his prints, not because he lost faith in it, but because, printing extensively, his assistants complained of the effect of the ether. He now uses the wax instead. Any trace of iodine in collodion for prints would be injurious. The bees'-wax treatment is cheap. 3. We saw the portrait to which you refer, and noted, also, the want of honesty to acknowledge it. Such a copy, unacknowledged, is, of course, piracy.

**W. A. (Southampton).**—We addressed the note and forwarded it. You are probably aware that the firm is passing through the Bankruptcy Court, which may account for the delay to which you refer.

**W. N. AND S.**—The ridge-roof form is best, placing the side towards the north. This is the form and position employed by the best men. 2. The decision as to the use of wood or iron depends upon circumstances. We should prefer wood to iron; or, if we employed iron, we should have it lined with wood.

**W. J. A. G.**—You will find the additional particulars you require, beyond those given by Mr. Bolton, in our YEAR-BOOK for 1866. A 15-grain tannin solution may be used. The difficulty in sending out collodio-bromide of silver ready for use consists in the fact that it is apt to precipitate in process of time, and, as Mr. Bolton states, should not be prepared more than a few days before it is required for use. We are not aware that any maker prepares a collodion especially suited to the purpose, but should think that most good samples of plain collodion might be employed. It is probable that the bromized collodion might be kept ready for use, and the requisite amount of silver added when required. If highly rectified solvents were employed in preparing the collodion, silver might be

used in the form of a saturated aqueous solution, one ounce of nitrate of silver dissolved in one ounce of water. 2. The so-called moonlight scenes produced by photography are generally instantaneous pictures by sunlight, kept in a low tone. Mr. Breeze states that he has absolutely photographed a white statue by the light of the moon with a long exposure.

**X. Q. P.**—The complete picture, and not every separate negative from which it was produced, will need to be registered. You may describe it as you mention, and register it as one picture. The smaller copy of it will not need registration. It is the design you protect, and not the especial size in which it is produced. A copy in any size, without your permission, will be a piracy.

**J. L.**—By proper precautions a wet plate may be kept a couple of hours between preparation and development. By Mr. Blanchard's method, recently described in our pages, he has succeeded in keeping a plate longer than that. But although a plate may be kept that time, it would be difficult to keep foliage still for half of that time; and unless the attempt were made in a light unfit for the work, or with imperfect appliances, foliage should never need anything like such an exposure by the wet process. You are probably right on the personal question; but it is better let alone.

**R. M. T.**—The turbidity and precipitate formed in your collodion on the addition of more bromide of cadmium was probably bromide of potassium, which is very sparingly soluble in ether and alcohol. When a collodion is iodized with a potassium salt, the addition of bromide of cadmium will frequently form bromide of potassium, which, if in greater proportion than about half a grain to an ounce, will generally precipitate. After the collodion is settled it is better to pour off the clear portion than to filter. The collodion so prepared will probably give you great vigour and brilliancy, but a little less harmony than one containing more bromine. 2. The more bromide present in your collodion, the more nitric acid you may have in the bath, without loss of sensitiveness.

**OUT-OF-FOCUS.**—In your description of your studio you have left all the dimensions blank, and so left us in ignorance of a great part of what you intended to state. Judging, however, from the portraits and from the view of your studio, you are suffering from insufficient light. It seems that you are so closed in that scarcely any direct light can reach your sitters. To satisfy yourself of this, place yourself in the position of the person standing for a portrait, and then look up and around, and ascertain how much sky you can see, for that will enable you to estimate how much direct light from the sky reaches your sitter. We fancy that you will see very little. The staining of the interior woodwork is not a matter of much moment. After two o'clock in the afternoon of this season the light is fast waning, and under the best of circumstances the light at that time would not be very good. We cannot give you any opinion of the lenses; they may be good, but those of most French makers, being cheap, are a little uncertain.

**VARNISH** is disposed to have a good-natured laugh at Dr. Mann for regretting the loss of negatives by the adhesion of the paper to the varnished film when exposed to the roasting in the direct solar rays of South Africa. Certainly the test was a severe one, but one which, we fancy, a thoroughly good varnish made of lac would stand without becoming sticky. Many varnishes in the market will not stand the direct solar rays of our own temperate climate.

**STILL.**—The disagreeable smell emitted on first using your tin distilling apparatus arises from the oil and resin used in the manufacture of the tin plate and in soldering the joints. It is not wise to employ soda for removing them, since this alkali attacks the coating of tin, and renders the metal afterwards liable to rust. It is a common practice to boil a little bran with the first water in new tin saucepans; but we should advise the rejection of the first few gallons which come over, and rely upon ordinary use as the best means of thoroughly purifying the apparatus from such adventitious matters. The cost of a 2-gallon tin still and condenser may be quoted at a guinea, or rather more, according to the substance of the metal.

**VENATOR.**—Thanks for a sight of the box. It appears admirably adapted to the conveyance of plates of various sizes. It would not pay you to protect it in any way, but you might show it to some dealer, and arrange with him to make it.

**GERMANICUS (Bangalore).**—Your interesting letter, enclosure, and photographs duly received. We will examine the prints and reply in detail shortly. The NEWS, &c., shall be duly forwarded.

**G. LEWIS.**—Our fourth volume is unfortunately quite out of print. We are glad that you find our Art Lessons profitable.

**C. R. LOBB.**—Thanks. We shall make use of your suggestions in our next. The prints are good and interesting.

**J. S. (Glasgow).**—We will ascertain, and communicate with you.

**A. B. C.**—We should think it quite safe.

**J. B. N.**—Thanks. Answer in our next.

Several Correspondents in our next. Several articles in type are compelled to stand over until our next.

## SULPHUR COMPOUNDS IN MOUNTING-BOARDS.

THE presence of hyposulphite of soda in the cards used for mounting photographs has been repeatedly noticed as a source of fading; but the extent of the mischief arising from this source, it is to be feared, is not realized by photographers generally. The number of instances which have recently come under our attention in which disastrous discolouration and fading in prints was directly traceable to this cause induces us to offer a few further remarks on the subject, with a view to urge upon our readers a more careful examination of the cards upon which valuable photographs are mounted.

Mr. England recently called our attention to a curious and annoying illustration of the injurious influence of the mounting card. Of a series of his Swiss stereo views, produced and printed some years ago, some were divided and mounted on white cards, the prints being four inches by three; whilst those intended for stereoscopic slides were mounted in the usual manner on yellow enamelled cards. Having occasion recently to examine some of the small single views which had been packed away, he found, to his surprise and chagrin, that they all showed unmistakable signs of fading, especially noticeable in the yellowness of the whites and lighter tones in the skies. On examination of the stereoslides produced at the same time, on the same paper, with the same solutions, from the same negatives, mounted at the same time and in the same manner, and kept in the same place, he found that these were in perfect condition, showing no signs of fading whatever. Every circumstance in relation to the fading and the perfect prints was precisely the same, except the kind of mounting card used. The stereo slides, as we have said, were mounted on the yellow enamelled cards commonly used for that purpose, and the single prints on white cardboard of apparently good quality. On testing the latter, the unquestionable presence of hyposulphite of soda was manifest, although in much less proportion than in many samples we have examined.

It is noteworthy that it is in the whites of the picture that the action of sulphur was most decidedly manifest. In some cases the blacks were vigorous, fresh, and perfect in colour, suggesting that the trace of un-reduced silver in combination with the albumen, not removed by the action of the fixing bath, was most readily acted upon by the sulphur compound in the card, whilst the blacks formed by a thicker layer of reduced silver and gold remained unchanged.

Where the hyposulphite or other sulphur compound is present in larger quantities, however, all portions of a print readily show its action. We have, on several recent occasions, had mounted prints sent for examination, in which, within a few weeks after mounting, the whole of the image was changed, the whites having assumed the well known

unpleasant yellow tint, and the blacks the greenish brown or olive tint common to the silver print in an advanced stage of sulphurization. In all these cases the plentiful presence of a sulphur compound was readily detected.

We use the term sulphur compound in the cards, instead of hyposulphite, as answerable for this disastrous action, because, whilst the evil is most commonly traceable to the latter salt, it is not the only substance used in the manufacture of paper and mounting cards capable of exercising the injurious action to which we refer. In order to secure the pure cold white, or white inclining to blue, of some papers, ultramarine is added to the pulp in the process of manufacture, and as this substance contains sulphide of sodium, its presence is dangerous in a paper or card intended for any photographic use in which it can come into contact with the salts of silver.

The simplest test which the photographer can employ to ascertain the fitness of a mounting card for photographic purposes will indicate the presence of either of the sulphur compounds to which we have referred. In the majority of instances of unsuitable cards which have come under our notice the application of a drop of a 10-grain solution of nitrate of silver is followed immediately by the appearance of a brown stain, which should lead to the unhesitating rejection of the card. In some cases no stain is produced immediately, but if the card be moistened with the silver solution and put away in the dark for a quarter of an hour, after which time the yellow brown stain will indicate the action of sulphur if present. Another mode of using the same test, involving a little more trouble, but more satisfactory when a small portion only of the hyposulphite is present, consists in soaking the suspected card in water for a few hours, and then adding to the water, in a test tube, a few drops of the silver solution, the appearance of the brown discolouration indicating the presence of hyposulphite. The only circumstance which would be likely to render the use of nitrate of silver doubtful in detecting the presence of a sulphur compound would be the presence of caustic lime, which is, we believe, used at times in manufacturing paper, to give fictitious substance and weight. This, by producing oxide of silver, would also cause brown discolouration, but the error would be of little importance in a practical sense, since it would only lead to the rejection of a card of very doubtful fitness for mounting photographs.

Where the photographer is desirous of employing a more delicate test for the presence of hyposulphite, nothing can be more simple and accurate than iodine for the purpose. Make a solution as follows: iodine one grain, iodide of potassium two grains, dissolved in distilled water one pint. Add a few drops of this, sufficient to give a delicate blue tint to a very dilute solution of arrowroot, and fill two test tubes with the pale blue solution. To one of these add a little of the water in which the suspected card has been

soaked, and add an equal amount of pure water to dilute the iodine and starch solution in the other tube. This will permit an accurate examination of the change effected by hyposulphite if present in the water in which the card has been immersed. Hyposulphite of soda will quickly remove the blue tint of the solution to which it is added by combining with the iodine; and any degree of change will be readily observed by comparison with the other tube held by its side as a standard.

To ascertain if ultramarine is present in the mounting card another mode of testing is necessary. Ultramarine, being a furnace product, is indestructible by fire. The suspected paper or cardboard to be examined should be reduced to a charred mass by burning in the air, and then introduced into a crucible and further heated until all the carbon is consumed. If the ultramarine is not already visible in the ash by its colour, the blue particles should be sought for with the aid of a lens or microscope. A characteristic property of ultramarine is the change in colour from blue to white, accompanied by the evolution of sulphuretted hydrogen when moistened with an acid.

The photographer has, of course, no control over the manufacture of mounting-boards, but he can exercise a power of selection and rejection; and the facts which have repeatedly come under our attention point to the importance of doing so. Of late, the increase in the consumption of hyposulphites as "antichlor" in paper making is stated to have advanced in enormous ratio. It is probable that if the protest of photographers against its use in the papers and cards to be used in photography were made sufficiently loud and urgent to be heard and understood by paper manufacturers, that other substances would for their purposes be employed. Sulphite of soda, or of lime, for instance, would absorb chlorine with formation of sulphates of these bases, which would be harmless. That of lime is occasionally used, we believe, in giving whiteness to paper, and its presence might be regarded as in no wise injurious to the photograph.

#### PHOTOGRAPHY AND DISEASE.

MR. CAREY LEA, commenting in the *Philadelphia Photographer* on the recent communications in our pages on this subject, considers the question is so important that if an article were written monthly on this subject it would scarcely be too much. He remarks:—

"It is not in the least difficult to explain loss of health as occasioned by photographic pursuits. All physicians know that the proper ventilation of the blood through the lungs is one of the most indispensable conditions of health, and that continued exposure to vapours not in themselves usually considered poisonous produces most injurious effects. Such vapours are, for example, fumes of ammonia, or of carbonate of ammonia, vapour of acetic acid, fumes of alcohol, or of benzene. The vapours of ether and of nitric acid are now too generally recognized as poisonous to render it necessary to say much about them, and any one exposing himself to their influence must necessarily expect to suffer."

"In a word, the lungs were made for inhaling pure air, and when they are compelled to take in chemical vapours, the load the system has to carry is just in proportion to the extent to which the air is vitiated."

"It is so difficult to produce an impression in these respects, that if an article were written monthly on this subject it would scarcely be too much. But just at present is the moment when caution is most needed. In the spring and autumn there are periods when the weather is too warm for fires and too cool to work with open windows. At such seasons, rooms have unusually little ventilation; in winter the fire keeps up circulation, and in summer open windows maintain a draft. At the intermediate period there is more than usual evil from vitiated air, and unusual caution in avoiding its deterioration is called for."

"Therefore, the photographer at such times should rather maintain his fires, and keep the temperature down by opening windows freely. In fact, the safety of the photographer will always largely depend on habituating himself to a constant movement of air."

#### LOSS OF SENSITIVENESS IN DRY PLATES.

PROFESSOR TOWLER, in recording the results of some comparative trials of dry plates, states his conviction that most dry plates lose sensitiveness by keeping. The plates tested were prepared by England's modification of the collodio-albumen process, by Col. Baratti's coffee process, and Bartholomew's morphine process. The experiments were tried in winter, the exposures made in a good diffused light the day after the plates were prepared. All the plates, having been exposed for the same time with the same lens and under all the same circumstances, were developed with a nitro-gelatin iron solution. The morphine plate could not be brought to the proper intensity without pyrogalllic acid. Upon the whole, he states, that of the three, the coffee plate was the softest, cleanest, and best negative.

After the lapse of another day he exposed three other plates; but the time of exposure had to be lengthened for all of them by two or three minutes. The results with albumen and coffee were in this case about equal. The morphine plate is stated to have come out just as rapidly as the other two, but stopped short in the development as before, and pyrogalllic acid and silver had to be used again.

On the third day the exposure had to be twelve minutes for each plate; with less time the impression was feeble. For several days the experiments were continued, and during the whole time they had to make a like increase in the time of exposure, in order to get tolerable results. As time progressed, coffee began gradually to fail.

On the eighth day a pair of each of the three plates were exposed for twenty minutes: the albumen plates gave results clear and distinct, but under-exposed; whilst from the others the pictures could not be forced into anything worth keeping: they are described as "complete failures."

Professor Towler concludes:—"None of these plates can be said to retain their sensitiveness beyond a few days; and, in a practical way, I would not think of trusting them beyond the second day. I believe they owe their sensitiveness to a retention of moisture in the film, and not to any preservative with which they are imbued. The albumen plates preserve their working powers the longest. The coffee plates are easily prepared, and, when used the next day, are reliable, and produce excellent results. I do not like the morphine plates, although they are very sensitive soon after preparation—you cannot force the pictures easily. Of course I have reference in these observations to the peculiar mode of development; my aim is to develop both wet and dry plates with the same developer (protosulphate of iron)."

#### EGG-ALBUMEN, FROM A CHEMICAL POINT OF VIEW.

BY JOHN SPILLER, F.C.S.

On a recent occasion it has been proposed to employ the white of egg in a naturally moist condition as the standard of comparison in estimating the quality, or degree of impurity, of potable waters, as regards their nitrogenous organic constituents. Variations in the amount of nitrogen contained in the white of egg have, however, been admitted, and the proportion of water, or, in other words, the weight of dry albumen, is suspected to be subject to variation. Whilst engaged in some experiments upon this new method of water analysis, in which, as I have said, albumen is taken as the starting point, and its nitrogen (or a known fraction of it) is evolved and estimated in the form of ammonia, it

appeared to me desirable at once to ascertain whether or not the moist contents of the egg lost water by evaporation through the calcareous shell; for if this be the case to any appreciable extent, the constitution of the albumen within cannot possibly remain for any length of time fixed and definite, although the egg itself may, during this period, be perfectly preserved from organic decomposition.

My affirmative anticipations on this point were based upon the circumstance that a new-laid egg exhibits no cavity on breaking the shell, whilst a stale one always contains a considerable air-space; however, to set the question at rest, I made the following experiments:—The weight of a hen's egg was exactly taken, and it was then supported upon a wire tripod-stand, so that the air might have free access to the whole external surface of the shell. Upon weighing the egg after an interval of twenty-four hours it had lost exactly one grain, and this ratio of loss by evaporation remained tolerably constant during several days. As, however, the experiment was made in the winter time, and during a season of wet weather, I repeated it under somewhat modified conditions. Two new-laid eggs of large size were taken, and, after their weights had been accurately determined, they were supported in a similar manner within a bell-jar, resting on a flat glass plate, with a dish of concentrated sulphuric acid to absorb the water given out by the eggs. The whole arrangement (that is to say, the dessicator and its contents) was placed in a room the temperature of which was maintained pretty uniformly between 55° and 60° Fah., and there left for six weeks, the diminution of weight being frequently observed during this interval. In all, ten weighings were taken, and the results proved that 100 grains, or more, of water can be abstracted under these circumstances, whilst the loss in the intermediate periods followed a diminishing scale, but nearly coincided with the several intervals of time. The average loss of water by evaporation through the shell may be stated, for the two eggs operated upon, to have been at the rate of 2 and 2½ grains respectively per diem. Upon breaking the eggs at the end of six weeks, one was found perfectly sweet and good, with the envelope of the yolk unbroken, but the second and smaller one was discoloured next the shell, and the albumen had become slightly decomposed. The last results with this egg were consequently disregarded.

The details of the experiments are quoted, for they serve to show the proportion of yolk to white at the final stage; ratio of water evaporated to total liquid contents; and the exact weight, in each instance, of the shell with its lining membrane, after careful washing with dilute ammonia and subsequent drying in the air:—

Egg—No. 1.			
Original weight (entire) ...	...	975.0	grains
Loss of weight in six weeks (water) ...	...	100.0	"
Shell and membrane ...	...	99.2	"
Yolk ...	...	317.2	"
White (by difference) ...	...	458.8	"

Egg—No. 2.			
Original weight (entire) ...	...	930.6	grains
Loss of weight in three weeks (water) ...	...	41.6	"
Shell and membrane ...	...	85.2	"
Yolk and white ...	...	803.8	"

It will here be noticed as an anomaly that the heavier shell of No. 1 egg permitted a faster rate of evaporation through its substance than No. 2. The latter appeared, however, upon inspection, to have a smoother external surface, and to be stronger and more compact in structure throughout.

The following table shows the actual amount of water lost by evaporation in the two instances for the intervals of time specified in the first column.

Loss of Weight in Dessicator (Water evaporated).			
Intervals of time.	No. 1 Egg.	No. 2 Egg.	
Days.	Grains.	Grains.	
1 ...	3.4 ...	2.6 ...	
2 ...	6.9 ...	4.7 ...	

Intervals of Time.	No. 1 Egg.	No. 2 Egg.
Days.	Grains.	Grains.
7 ...	17.3 ...	14.0 ...
14 ...	34.3 ...	27.6 ...
21 ...	51.1 ...	41.6 ...
42 ...	100.0 ...	— ...

Ratio of Water Evaporated to Total Liquid Contents of the Egg (per cent.).

Time.	No. 1.	No. 2.
In two weeks ...	3.9 ...	3.3 ...
three " ...	5.8 ...	4.9 ...
six " ...	11.4 ...	— ...

It would be difficult to prove whether or not the water lost by evaporation from the white is partly compensated by an accession of water, by diffusion, from the yolk. No colouring matter travels outwards unless an organic decomposition sets in, when all the natural barriers are destroyed, and the several parts of the egg become merged. I am inclined to think that this re-distribution of water actually occurs, since the *sac* of the yolk appears wrinkled in a stale egg, as though by loss of a portion of its liquid contents.

The composition of fresh egg-albumen may be said to vary between the following limits:—

Water ... 88 to 85 per cent.

Dry albumen (containing nitrogen 1.55 to 1.75 per cent.) ... 12 to 15 "

Other analyses have been recently published, in which the nitrogen amounts to 1.81 per cent. and upwards, with the minimum proportion of water. It is probable that these latter results were obtained with eggs which had been longer kept in stock.

The indications of change in the composition of egg-albumen by evaporation of moisture are not, perhaps, so decisive as to interfere greatly with the ordinary operations followed in the manufacture of albuminized paper; the protracted exposure of large surfaces of diluted albumen in shallow dishes left freely open to the atmosphere of heated rooms must induce a more rapid increase in concentration of the albumen than is ever likely to occur as the result of the natural dessication of the egg. The relation subsisting between the yolk and white in different eggs appears to vary between somewhat wide limits; and the most remarkable monstrosity that ever came under my notice was a double egg, united at the smaller extremities by a membranous ligature, and without any shell; the one *sac* containing all the yolk, and the other only the white. This was laid by a hen belonging to a member of our staff, and we have had it since August, 1866, preserved in spirit. It lost water rapidly during the short interval previous to immersion, and the yolk half seemed from the first to be less expanded than the twin *sac*. From the circumstance that it remained so in any position we inferred that there was no communication between the two receptacles. It should be mentioned, in conclusion, that these latter were of the ordinary size. I send you a stereo photograph of this interesting object.

## THE NEW PHOTOMETER.

BY DR. VOGEL.

My new photometer is intended for measuring the time of exposure for negatives in all the photographic processes in which the image is not obtained by direct operation, but is brought out afterwards by a development; such processes, for instance, as the carbon printing process (one of the most important applications of the instrument), enamel process, aniline printing process, photo-lithography, for the production of negatives, &c.

The photometer consists in a transparent scale, made from a prepared paper, graduated in strips, the thickness increasing in an exact mathematical proportion from one end to the other. Under this scale is exposed a strip of bichromated paper—Saxe paper, immersed in a 1:30 solution of bichromate of potassium for two minutes, and dried afterwards. This

paper keeps its qualities very well for some weeks, and is as sensitive as silver paper, and it is darkened by the light to a tint deep enough for photometrical purposes.

If such a strip of bichromated paper be exposed under the transparent scale, the strip is darkened by the light, at first under the thin end of the scale, and this colouration will advance to the thick end of the scale, in ratio corresponding with the actinic quality of the light. For recognizing exactly the point to which the action of light is advanced, numbers are printed on the transparent scales in opaque ink, which retards the action of light, and causes the numbers to appear white on the sensitive paper.

The instrument is like a printing-frame, but with an arrangement to open it from the glass side for observing the number made visible by light on the bichromate paper. The bichromate paper is cut in strips corresponding with the length of the inner case C, which is, for placing in the strips, opened from the lower part; the dotted piece of wood, *h*, is re-

moved, and the sensitive strips are laid one on the other in the case, which is then closed. In this manner the paper strips are pressed by the elastic (dotted) spring *f* against the upper side (open in the figure), and if the cover *D* is closed (by aid of the catch *x*), the strips are pressed against the transparent graduated scale. This scale is fixed on a glass strip which forms the upper part of the cover *D*. A second cover, *L*, of wood, serves for exposing the transparent scale to the light when it is necessary to make an observation or examine the bichromate strips by lamp-light.

For employment in carbon printing, this photometer is brought to the light at the same time as the printing-frame with the negative, which is allowed to remain exposed till the instrument indicates 10, 12, 14 degrees, according to the thickness of the negative and the sensitiveness of the carbon paper (16° in employing Swan's paper for a medium negative).

The method employed for fixing upon the number of degrees requisite for printing any negative is very simple. My own negatives I can at once, on inspection, divide into three classes, viz., thick, thin, and medium; and in order to fix the degree of intensity I take a carte-de-visite negative containing three or four pictures of equal density, and expose it to the action of light with a piece of carbon paper. When the photometer, which is exposed at the same time, indicates 10°, I cover up one of the pictures; at 12° I cover a second; and at 14° a third. Whichever degree of intensity gives the best picture on development is the one best suited for the negative under examination, and others of a similar thickness. To ascertain the printing degree in other negatives I proceed in the same manner, a small strip of sensitized paper only being required for each experiment, just sufficient to cover a thin section of the negative. When the degree of a negative has been fixed upon, I mark the latter with the number. A little experience in the use of the photometer and the carbon process will enable the operator to ascertain the requisite degree of any negative by simple inspection; and when this has been ascertained, the process is very much simplified, for, as Wilson remarks very truly, "if the exposure is correct, the print cannot fail to be a success."

It may be supposed that one photometer is required for

every copying-frame; this is, however, by no means necessary, if a systematic method of working be adopted. A number of frames are furnished with sensitized paper, and brought into the light at the same time, together with a photometer; and when the instrument indicates the degree of intensity necessary for the printing of the thin negatives, the latter are either turned over or removed, the thicker negatives being treated in the same manner when the photometer indicates that they have also been sufficiently exposed. In favourable weather the whole batch will be printed in a few minutes, and attention must therefore be paid to the photometer, in order that the negatives may be covered up at the proper time. As many as ten prints may sometimes be obtained from a thin negative in one hour. If the prints are required in a hurry, and it is necessary that no times should be lost in the printing, it is as well to have one photometer for each of the three descriptions of negatives (viz., for the thick, thin, and medium); but even by this arrangement only three instruments are necessary.

There is one more point still to be considered, and that is, the sensitiveness of the carbon paper, which differs greatly according to its manufacture, that exported from America being almost double as sensitive as that made in England. To ascertain the sensitiveness of a new paper, it is necessary to make an experiment, in the manner above described, with a negative of which you already know the printing degree. For instance, if, with American paper, a negative is known to have the printing degree of 10, and with the new paper the degree is found to be 12, then the degrees for all other negatives must be added when printing with the new paper.

The reason of this simple calculation is, that the degrees of transparencies of the scale are in an exact mathematical proportion, the proof of which I will give to you as shortly as possible.

Imagine a series of transparent strips of absolutely the same quality—for instance, mica, glass, paper, &c.: if the light goes through a series of such strips, its intensity is diminished by reflection and absorption. This diminution will be the greater if the number of strips is larger. Suppose the intensity of light which falls upon the upper strip will be = 1, and the diminution by going through one strip is such that the original intensity is reduced to  $\frac{1}{n}$ , then the

diminution will be, after gone through—

$$\text{the second strip} = \frac{1}{n} \times \frac{1}{n} = \frac{1}{n^2};$$

$$\text{the third strip} = \frac{1}{n^2} \times \frac{1}{n} = \frac{1}{n^3};$$

$$\text{the fourth strip} = \frac{1}{n^3} \times \frac{1}{n} = \frac{1}{n^4};$$

therefore, if you construct a layer of strips like a staircase,

the intensity of light after gone through will be—

1	2	3	4	5	6	...	...	9 strips
$\frac{1}{n}$	$\frac{1}{n^2}$	$\frac{1}{n^3}$	$\frac{1}{n^4}$	$\frac{1}{n^5}$	$\frac{1}{n^6}$	...	...	$\frac{1}{n^9}$

that is, the intensities of light gone through such a layer of strips form a geometrical series.

Now, if the intensity of light is reduced in such a manner whilst going through the strips, it is very easy to conceive that the quantity of chemical (actinic) light which must fall upon the layer of strips for making a visible impression on chromate paper, which is situated under the strip, must be larger in the same proportion as it is reduced whilst going through the strips. It is demonstrated that the diminutions are in the proportions—

$$\frac{1}{n} : \frac{1}{n^2} : \frac{1}{n^3} : \frac{1}{n^4} : \frac{1}{n^5} : \frac{1}{n^6} \dots \dots \frac{1}{n^9}$$

therefore, the quantities of actinic light necessary for making a visible impression under one, two, three, . . . 9 strips, will be—

$$n, n^2, n^3, n^4, n^5, n^6 \dots \dots n^9;$$

that is, the quantities of light indicated by the appearance of the degrees of the photometer form a geometrical series, of which the numbers of degrees are the exponents.

From this law you now make a very important conclusion for practice; for you receive a new paper with another degree of sensitiveness. You have not necessarily to determine by long experiments the printing degrees for the new paper; but it is sufficient to make a single experiment with a single negative, in the manner before described. If the printing degree for this negative on the old paper was, for instance, =  $p$ , and for the new paper you find, for instance, the printing degree =  $r$ , then the quantities of light for printing out the same negative on old and on new paper, are in the proportion—

$$n^p \quad n^r = \frac{n^r}{n^p} = n^{(r-p)}$$

therefore, if you will make a print on the new paper it follows that you have necessarily a quantity of actinic light, which is for  $n^{(r-p)}$  times larger than the quantities necessary for printing on old paper. For this reason, if the printing degree for any negative for old paper was, for instance, =  $v$ , then the quantity of actinic light necessary for printing out on old paper this negative was  $n^v$ ; and if you will make from this negative a print on new paper, you have necessary a quantity of light, which is  $n^{(v-p)}$  times larger; that is, =  $n^v \times n^{(r-p)} = n^{v+(r-p)}$ .

Now, the exponents  $v$   $r$   $p$ , &c., are the numbers which I name the printing degrees; therefore, the printing degree for the negative above mentioned is =  $v + r - p$ , and from this follows:—

If you will have the printing degrees for any new paper, for all the negatives, from which you know already the printing degrees for an old paper, you only add the difference between the two printing degrees, determined by a single experiment with a single negative to all known printing degrees of all your negatives.

I use the instrument for carbon printing chiefly. For observing the number made visible by light a little practice is necessary. Recently I have used the instrument also in reproducing photographic enamels, with the process Obernetter or Joubert; also for making aniline prints (process Willis). A transparent glass positive gave a well exposed aniline print with 8° of my photometer; the same positive gave an image for enamelling (process Obernetter) with 15° of my photometer. This shows that the aniline printing process is much more sensitive than the Obernetter enamel process and the carbon process. For the latter, the printing degree for a medium negative on Swan's paper = 16°; on Rowell's = 11°. For photo-lithographic and similar purposes, I shall try the instrument shortly. For determining the time of exposure in producing negatives, the mode of using the instrument is a little different from the way above mentioned. Here a table is necessary, calculated by myself, which I shall publish another time.

# PICTORIAL EFFECT IN PHOTOGRAPHY; BEING LESSONS IN COMPOSITION AND CHIAROSCURA FOR PHOTOGRAPHERS. BY H. P. ROBINSON.

## CHAPTER XI.

"Many are the landscape painters who seem, in their studies from nature, as if they had never raised their eyes above the horizon; and among the proofs of the indifference of those who interest themselves in art to the beauty that canopies the earth, may be noticed that, although the composition and light and shade of clouds are as much within the reach of the photographic art as any of the other great things of nature, they are her only beauties it has hitherto neglected. I have seen but two calotypes of skies, and these prove that it is from no want of power in the process that

skies are not as common in our photographic exhibitions as any other subjects."—*Leslie*.

"To admire on principle is the only way to imitate without loss of originality."—*Cotteridge*.

## THE SKY.

WHEN Mr. Leslie wrote his Hand-Book for Young Painters, from which one of the above quotations is taken, very little had been done towards the photographic representation of cloudland. I shall always esteem it one of the proudest recollections of my life that I had the honour of knowing this great painter—one of the greatest England has produced. He always took great interest in our art, and it was a good deal by his kind appreciation of my earlier efforts, and encouragement against much opposition, that I persisted, whether rightly or wrongly, in my endeavours to make photography the vehicle of pictorial effect.

But this is commencing with a digression, all the more objectionable because it is personal. Dealing with this part of my subject affords me an opportunity, however, of which I avail myself as a pleasure and a duty, to record a personal knowledge of the interest taken by this great painter in the art-capacity of photography.

Since the time when the Hand-Book was written (1854) photographers have, it is true, turned their attention to the sky, but only in a fragmentary sort of way, and not with a steady determination to make the most of it in their pictures.

The importance of the sky as an aid to effect in landscape cannot be over-rated. In a letter to a friend, quoted in the work I have just mentioned, Constable, who was an enthusiastic admirer and follower of nature in his works, and who spent entire summers in painting skies, thus writes, and his observations should be taken to heart by all landscape photographers:—"That landscape painter who does not make his sky a very material part of his composition neglects to avail himself of one of his greatest aids. I have often been advised to consider my sky as 'a white sheet thrown behind the objects!' Certainly, if the sky is obtrusive, as mine are, it is bad; but if it is evaded, as mine are not, it is worse; it must, and always shall, with me, make an effectual part of the composition. It will be difficult to name a class of landscape in which the sky is not the key-note, the standard of scale, and the chief organ of sentiment. You may conceive, then, what a 'white sheet' would do for me, impressed as I am with these notions—and they cannot be erroneous. The sky is the source of light in nature, and governs everything; even our common observations on the weather of every day are altogether suggested by it. The difficulty of skies in painting is very great, both as to composition and execution; because, with all their brilliancy, they ought not to come forward, or, indeed, be hardly thought of, any more than extreme distances are; but this does not apply to phenomena, or accidental effects of sky, because they always attract particularly."

Although I do not think it advisable to make a too liberal use of quotations, I cannot forbear adding Leslie's own testimony to the value of the sky, and which contains a very beautiful thought:—"Rocks, trees, mountains, plains, and waters, are the features of a landscape, but its expression comes from above; and it is scarcely metaphorical to say nature smiles, or weeps, and is tranquil, sad, or disturbed with rage, as the atmosphere affects her. Hence the paramount importance of the sky in landscape—an importance not diminished, even when it forms but a small portion of the composition."

It often occurs that a view must be taken of a scene that composes badly, and of which, from accidents of the ground, it is impossible to select another point of view. The artistic photographer now has his remedy in the sky, and if he understands the use of it for producing pictorial effect, he may redeem the ugliness of a scene not worth photographing for itself, but which may be interesting from its associations.

The sky is the natural background of the landscape, and should be of the same use to the landscapist as a background

is to a portrait photographer, and should not be regarded as so much waste paper, as is too frequently done, but it should be made to throw out and relieve the principal subject, by the direction of the cloud lines opposing the lines of the landscape, by the opposition of light and shade, either to produce relief or breadth, and to generally assist in the production of pictorial effect: unless, indeed, as sometimes occurs—a fine sunset, for example—the sky be the chief object represented; then the landscape must be subordinate.

Leaving out of consideration the latter case, let us see how far its employment as a means of effect is legitimate, especially when printed from a separate negative to the landscape to which it is joined in the finished print: the only way, in my opinion, by which the fullest value can be obtained, and the utmost amount of pictorial effect can be produced; and that not by blind chance, of which Ruskin tells us to be independent—as would be the case if taken with the landscape—but with that certainty which a knowledge of art give to its votaries. It will not be necessary to give any definite instruction for the use of the sky, as the readers of these articles will, by this time, or after they have read the chapters on *chiaroscuro* which are to come, be able to artistically apply an object that is infinitely varied, to suit all circumstances of composition, and is for ever changing in its light and shade and form.

Many ingenious arrangements have been devised for the purpose of securing the sky on the same plate as the landscape, and I believe there are now no chemical or mechanical difficulties in securing the two by one operation which a clever photographer could not successfully combat; but before you cook your hare you must first catch it. Now, however natural any sky that may happen to be in the heavens at the time the photograph is being taken, it only occasionally occurs that it is the best, or nearly the best, for pictorial effect. This being the case, it is for the operator to select a sky that will best suit his picture; and in doing this he must have a sufficiently critical knowledge of nature, and the various phases she assumes, to prevent him departing from the truth of nature. He must keep strictly to the truth of nature—that is absolutely imperative—but he may select the best and most picturesque nature he can get. The intelligent student will be ever on the look-out for what is beautiful, and when he sees a fine effect he will always examine the causes by which it is produced, and note them in his pocket-book, although he may not have his camera with him at the time.

What the photographer has to do, then, is to select and use a probable sky to increase the beauty of his work; but it must be such a sky as would render it impossible, not only for the carping critic, but also the real man of science, to say it is not true. It must, indeed, be so true as to defy the adverse criticism, as a fact, of the most learned meteorologist. Surely no very impossible task to an observing student!

While the foreground of a picture should contain the keynote of the composition, the sky should always preserve harmonious relation to the whole picture. The various effects of cloud and sky which may be introduced in landscape photography afford a vast scope for the display of the art capacity of the operator. He can, by a well-chosen effect, bring an otherwise unimportant and somewhat tame distance into better keeping with the remainder of the picture; he can by its means supply a deficiency in some of the most important lines of the composition; or he can, especially in pictures with figures in the foreground, use an effect of cloud or atmosphere to give not only relief to the principal object, but to correct the foreground and the distance; for although the sky is really behind the picture, still it may form the connecting-link between any two grades of colour or masses of light and shade.

Just a word in my next in reference to the absurd notions of those who hold—I can scarcely say believe—that the truth of nature is violated if a sky is added to a landscape from a second negative, and that those who select nature "maintain in idea that the artist is greater than the Divine

Maker" of nature, which they quote, and pervert to an unintended use, from Ruskin, and then, as far as this part of my subject is concerned, I have done.

## ADHESIVE MEDIUMS—A WORD OR TWO IN FAVOUR OF PASTE.

BY A PRACTICAL MAN.

As some little attention is now being directed to "india-rubber solution" and other adhesive mediums, a few hints may be acceptable in regard to the old domestic "familiar"—paste. Paste is considered a very simple thing to make. So it is, when you know how. Milk is a very simple thing to boil; potatoes not less simple; but how rare to find them properly prepared; the first without being allowed to boil over, and the second without being reduced to a watery smash! The general fault in paste making is in not having it sufficiently smooth and sufficiently boiled—not burnt. Pastes may be made of dextrine, rice, starch, or flour. Paste made with flour was extensively used by the old water-colour painters: Turner, Girtin, Varley, Walmsley, and others. If paste were guilty of all that is sometimes laid to its charge by photographers it could scarcely fail to injure the tints of many of the delicate water colours used by these masters in producing their charming effects. Yet their drawings in the folios and in the frames of collectors have suffered no further change than that of receiving the "golden tinge of age," a very different thing from the sickly yellow tinge of a decaying fading-away photograph. The greater part of the pictures alluded to have been in existence more than half a century, and, from their present perfect state and freshness, seem to have received but little or no harm that can be laid to the charge of "paste;" it being also a generally understood fact that Turner freely used paste to the backs of all his drawings, his fleecy cloud effects, &c., being produced on the fronts by copious washing and sponging.

To keep paste from becoming mouldy, put in a few shreds of isinglass and a little essential oil of cloves. A good serviceable paste is made by first preparing a bason or cup full of strong starch, according to quantity wanted, to be made with hot water poured from the spout of a tea-kettle with the steam well up. When the starch paste has become cold, put it into a wash-hand basin or pan, and rub well up with the hands—in fact, wash the hands in it; then return the same to the cup or basin, and put on one side to ripen. This will be known to have taken place when the paste loses its blue tinge, and becomes white. It will now be found as thick and smooth as butter, and can be spread over paper with the finger, so as to form a clean and even film. This paste may be mixed with prepared gum; one part gum to two of paste. The gum should be dissolved in clean soft water, and then strained through flannel for use.

A general mistake in the pasting process is that the paste is used too thin, and not allowed time to soak into the paper; but the moment the paste is applied down it goes, and then commences all the eel-like evolutions of twisting, turning up, and cockling. There is nothing more convenient for the photographer in pasting operations than the old "napkin press" of thirty years ago, when napkins and finger-glasses were in vogue. These presses have a drawer underneath, the bed of which is of inch-deal, on which is placed any article—napkin, book, paper, print, or cloth—that wants pressing to take out the creases and folds. A piece of board, somewhat smaller than the bed, is now placed over the articles, and the screw turned that works down from the top rail. This arrangement will allow the article to remain under pressure as long as may be needed, or till such time as they are firmly set and dry. Much of the failure attending adhesive methods and processes is more from the careless and slovenly way in which the thing is done than from the materials themselves. The addition of a few drops of the ten-grain solution of carbolic acid, as described in a

former number, will be of service in the gum and paste recommended above. A very useful and available article to keep paste, &c., in is one of the common mustard-pots that have covers fitted to them for keeping out dust and dirt. It is as well not to leave the brush in the paste, but to well wash it after using, and put by for another time.

### OUT-DOOR PHOTOGRAPHY.

BY J. R. HEATON.\*

As the time of the year is now fast approaching when photographers will commence active operations out of doors, I thought it would, perhaps, not be out of place to offer a few remarks on photography in the field, with a glance at the apparatus necessary for its prosecution by the wet process.

We will commence, then, with the dark tent. I have tried a variety of contrivances in the shape of boxes and tents of almost every description for the preparation and development of wet plates in the field, and I may safely say that I have found none so portable or convenient as the one now before you; it is so easily and quickly erected—not occupying more than two minutes—which I consider a very great advantage when you have to move about to so many different localities in a day. Too much attention cannot be given to see that each and every part of the apparatus is properly fitted and constructed, so that no accident may occur when in the field. I have some painful recollections of accidents which have happened during my experience in out-door work. How provoking to the ardent photographer when, after travelling miles away from home in search of the beautiful and picturesque, he at last comes upon some glorious landscape which he has often dreamt of, but never before seen realized—a wonderful combination of foliage, water, clouds, sunshine and everything that is grand and beautiful; there is not a breath of wind to disturb the most delicate blade of grass; the purest of light comes just in the right direction for giving the best effect to the scene; he is enraptured, and somewhat nervously commences operations by unpacking his tent and his chemicals—when, to his horror, he discovers that by some mysterious and extraordinary means the camera, lenses, plates, &c., are completely inundated. The screws of his water-tight bath have failed to perform the office assigned to them, consequently the nitrate solution has free access to the box and everything it contained: perhaps the glass dipper is broken, or the loose handle for focussing has been left behind, or lost, and you are thus debarred from proceeding any further until things are rectified, which is not always an easy matter when away from home. As Richard the Third, you might with propriety exclaim, "A screw! a screw! my kingdom for a screw!" It is a good plan, in fitting out an equipment, to provide a separate place for every article required, so that if there be any vacant places visible, the deficiencies can be at once filled up; and if there be any doubts whatever respecting the working qualities of either apparatus or chemicals, by all means try a plate before venturing away from home. It may save you from much useless labour, expense, and consequent mortification.

As to cameras, I think that for ordinary out-door operations there is nothing supercedes the binocular form with bellows body, rising front, swing back, hinged focussing-screen, and moveable central partition. In the camera before you—which I may here state is made by Mr. Rogerson, of Manchester—you will observe that with this camera long or short focus lenses can be used at will according to circumstances or requirements, which is sometimes a great advantage, especially when working in confined situations. The focussing is effected by means of a rack-and-pinion; it is more convenient to work, besides saving the extra expense in having a rack-and-pinion to every lens you use. You will also observe that it can be used either in a vertical or horizontal position, and that (unlike any camera I have

seen before) the rising front and swing back movements are available in both cases. It is constructed for plates  $7\frac{1}{2}$  by 5, and is suitable for a variety of work. It may be used both in the studio and the field, taking pictures the full size of the plate for stereo slides and cartes, the length of the plate enabling the operator to cut his carte prints either horizontally or vertically, whichever best suits the picture. He has also considerable latitude for stereos. One half the size of plate comes in very handy for book illustrations and for magic lantern slides. Another advantage is that, having only one size of plate, you only require one size of bath, plate-box, printing-frames, &c. As a rule, the tripods generally used for out-door photography are too low. I think that to give the best effect in most cases the camera should stand (say) from 5 feet 6 inches to 6 feet in height, which would be about the same level as is generally seen by the ordinary observer of nature. A longer tripod is very useful when you wish to operate over a wall or fence, or to plant in a stream or brook, as is sometimes necessary.

The landscape photographer should, if possible, provide himself with a number of lenses of different focal lengths, and have them ready for use as circumstances and occasion would suggest.

I think it would be unwise for me to recommend any particular formula for the production of negatives in the field, as so much depends upon the description of subject you may have in hand. You may wish to take a distant landscape, a group of cattle, a study of foliage, ferns or grasses; or, may be, an architectural subject; perhaps, a river scene, or a waterfall. And then, again, much depends upon the light, the temperature, and other things combined together, that I should consider it a piece of folly to recommend one particular formula or mode of working for anything and everything you may come across. Of course every photographer knows—or, at least, ought to know—the value and importance of keeping his chemicals in the best working condition possible. And should he have any particular formula or method of manipulating wet plates with proficiency and certainty, let him stick to it, and not allow himself to be led or carried away by the numberless formulas, processes, and their modifications, that are continually emanating from various sources. There are collodions, baths, developers, and in abundance; some collodions that are said never to fail in giving the best results, even in the worst of weather. Collodion is now manufactured for producing portraits *a la Salomon*. There are baths which never get out of order; and I have seen some that, judging from the plates which come from them, never were in order. There are developers of all descriptions and strengths, varying from 2 or 3 grains to nearly 100 grains to the ounce; some that both develop and intensify in one operation, and some that bring out nothing but fog, streaks, stains, spots, and dissatisfaction. There are processes and formulas enough to perplex and bewilder all who will go to the trouble and expense of trying them. It does not necessarily follow that because Mr. A. develops his negatives with a gelatine solution, and gets such beautiful results, that I, or anyone else, using the same developer, shall produce exactly the same, or even similar pictures; it is the knowledge of seeing and knowing what we most require, and adapting the same to our requirements. Why should every subject we operate upon receive the same mechanical treatment? The photographer should always have two or more samples of collodion of different characters, one giving a good creamy film, the other a thin one; these can be used in their original state, or mixed together, to suit any particular subject. A small bottle containing a concentrated solution of iron is also a very valuable acquisition for strengthening the ordinary developer, now and then, as occasion requires.

The facility of successfully developing a picture is one that requires a considerable amount of experience, as a negative is so very easily spoiled by under or over-development. In taking a landscape embracing some ten or twelve miles of scenery, the extreme distance being composed of mountains

\* Read before the Oldham Photographic Society, March 29th.

and clouds, in the middle distance we have a sheet of water, while the immediate foreground is made up of some dark objects, rocks, foliage, &c. If we expose a plate on this subject in the ordinary way, we shall probably find, on developing, that while the mountains and clouds in the distance are much over-exposed, the foreground has not been exposed sufficiently long to bring out any detail whatever beyond a general outline. There are two or three methods of remedying this evil: one is effected by means of a flap-shutter, which is fixed either inside the camera or in front of the lens. By these means the operator has sufficient control over his subject; whilst securing detail in the foreground, he does not sacrifice anything in the other parts of the picture, but all are harmoniously combined together.

Much can also be done by the judicious application of the developer, keeping the same more on the foreground, whilst the development of distance, clouds, &c. are held in check; then, again, in the printing, by skilfully masking the different parts of the negative that would otherwise become too dark.

Every landscape photographer should be in possession of a number of cloud negatives of different characters, so that he may always be able to introduce suitable skies in his pictures: they will be found very serviceable when printing from negatives which give white skies. Perhaps I shall have something to say on double-printing at some other time.

I shall not attempt to lay down any rules for selecting, arranging, and composing the landscape; but I would take this opportunity of recommending to all who take any interest in picture-making to read and study the excellent papers by Mr. H. P. Robinson, now being published in the PHOTOGRAPHIC NEWS. And, in conclusion, let me impress upon the minds of all present, who have not made a knowledge of art their study, to lose no time in cultivating it; and let each and every member strive to encourage, assist, and stimulate each other, and may we all endeavour to produce something worthy and more creditable both to ourselves, our art, and the Oldham Photographic Society.

#### ON THE CAUSE OF DETERIORATION OF PRINTS MOUNTED ON CARDBOARD WITH GILT BORDERS.

BY MM. DAVANNE AND FORDOS.\*

IN December last we communicated to the Society a few remarks on the appearance of certain spots upon carte-de-visite photographs, a cause of deterioration which was seldom met with on pictures of a larger description. These spots were of the most minute kind, and always became visible, in greater or less numbers, a short time after the pictures had been mounted. The cause of this alteration in the photographs was due, we opined, to the presence of metallic powder in small quantities upon the surface of the card-mount; having now completed a series of careful investigations in reference to the subject, we are now able to state positively that such is the case.

Our labours have been greatly facilitated by the kind assistance of our colleagues, who, readily responding to our call, have furnished us with information and subjects for examination. M. Dauvois procured for us samples of the different descriptions of powder used in gilding and ornamenting card-mounts, and MM. Quéval, Reutlinger, Cognac, and Jacoby, have forwarded examples of damaged pictures.

The injury is due, as we have before stated, solely to the presence of minute particles of metal which become attached to and attack the picture; it being unnecessary that the metallic powder should be mixed with any sulphurous compound. M. Quéval has furnished undisputed proof of this being the case by forwarding a few stereoscopic slides in which a perceptible line of these spots may be traced on the prints in those parts where a line of bronze is printed

underneath; a microscopical examination of spots of a similar character on carte photographs showed them to be due to the same cause.

If a little bronze powder is strewn over a piece of cardboard, even of the smoothest description, and then dusted off again, there remain in the pores of the cardboard small particles of bronze, which, although invisible to the naked eye, are very apparent with the aid of a microscope. A print mounted upon a card of this description soon becomes speckled, and the little spots, which appear white upon the surface, will be found to have a little black germ below, if the print is raised up by means of a needle point. The operations of mounting and rolling are often sufficient to remove a little of the powder from the bronze ornamental line round the picture; and these particles, becoming adherent to the surface of the print, likewise produce spots, but in this case the black germ will be found to be uppermost, and becomes visible immediately.

M. Jacoby forwarded to us carte pictures presenting the same obnoxious appearance, but mounted on cards not with gilt, but with red borders. We at first imagined that the ink used for these borders contained vermilion or sulphide of mercury, and that this was the cause of deterioration; the spots, however, were due, as in the other cases, to particles of metallic powder which must have become deposited on the prints during their sojourn in the *atelier*, or during their manipulation with the rolling-press (which had previously been used in finishing off pictures with gold borders); for an examination of the spots with the microscope betrayed the presence of minute particles of bronze not yet decomposed. A little dust collected in the *atelier* where the pictures were produced was found to contain a large quantity of these metallic particles.

The largest and best proof remains to be mentioned: a small quantity of bronze powder was strewn over a picture, and its action was then closely watched in a damp atmosphere. After a short time each metallic particle was found to have changed into a black speck, and to have become surrounded by a white halo presenting all the characteristics of the spots which form the subject of the present examination.

The explanation of the formation of these spots is very simple when we remember that the photographic image is composed, according to the researches of MM. Davanne and Girard, of metallic silver and an argento-organic compound, which forms the colouration of the picture. It is this argento-organic compound that is destroyed by the metallic particles, which exert a very rapid and intense action upon the print, especially when the latter has been insufficiently toned and washed.

#### CARBON PRINTING.

BY M. CAREY LEA.

ABOUT a year since I made some experiments towards the simplification of carbon printing, which I left unfinished, with the intention of returning to them at a future day; but I have not found the time, and M. Despaquis, in his experiments on mica printing, has hit upon an idea a good deal similar to that which I was working on. But my principle was of much wider application than his, so that, I believe, I may do some service in publishing it before some one takes out a patent for the idea.

It seems to me that if I could find a method of carbon printing in which the troublesome transfers could be done away with, carbon printing would be considerably simpler than silver printing, because of the absence of need of toning. This could only be done by printing through the support. I tried paper prepared in many ways (a method which Mr. Blair has long laboured at) without getting any satisfactory results, principally, I think, because the bichromate solution penetrates irregularly into the varnished or waxed paper, and renders it unqually adiacinic. Glass presented the difficulty that

\* Read before the French Photographic Society. See also p. 124.

in printing a negative, through even very thin glass used as a support for the sensitized pigment, the sharpness would be very much impaired.

Glass, however, offers such very great advantages, by reason of its perfect transparency and its cheapness, that it seemed very desirable to overcome this difficulty, and I succeeded in doing so perfectly. I found that by the device which I adopted I could print a portrait through a piece of plate glass upon a carbon surface so sharply that every hair was visible. This was done by using reflected sunlight—a species of illumination which, though occasionally used in the negative process (for copying Daguerreotypes) has, I believe, never before been used for positive printing, and certainly not for the purpose here proposed, and for which it answers equally well.

The best mode of proceeding is to place the frame holding the negative and the pigmented glass against the wall, beside a window at which the sun enters. Then let a mirror be placed so that the rays fall upon it almost perpendicularly, and are reflected full upon the frame. The sensitiveness of the bichromate is so much greater than that of silver paper that even in this light four or five minutes' exposure are sufficient with an easy-printing negative.

After printing, all that is necessary is simply to wash off the superfluous pigment, and the picture is finished. It is an exceedingly easy process, as will naturally appear from my description, and, what is no small matter in these days, can be practised by any one without infringing existing patents.

Transparencies printed in this way may be looked at through the glass, and thus are non-reversed. The method is, of course, not applicable to printing on opal glass, for the support must be transparent.

I cannot doubt that, with the aid of this plan of using reflected sunlight, modes will be found of working upon transparent paper, such as will give good results. All pictures on pigment, made without transferring, must in every case be reversed. If it is necessary to avoid this difficulty, the negative itself must be either reversed by taking it on the back of the glass in the camera, or, if made in the ordinary way, this mode of printing by reflected sunlight will enable the negative to be printed through its own glass, provided the latter is free from flaws and defects.

Obviously, however, the most useful application of this idea is to the printing upon thin plate glass, in the manner first above mentioned. Connected with this, a few words remain to be said as to the best method of preparing the glass for printing.

Of course the sensitive mixture can be poured out upon the glass. Mr. Swan, I believe, prepares all his "tissue" originally upon glass, and transfers it to paper.\* But as this operation requires a special manipulation not immediately acquired, it will be found simpler to purchase the pigmented paper, and apply it to the glass. And here a difficulty will be found. The "tissue" must of course be sensitized. If dipped into the bichromate solution and applied to the glass, it will be found wholly impossible to get rid of the small air-bubbles which form between the pigment and the glass. To avoid this, put the glass first into the pan of bichromate solution, then the pigmented paper, pigment side down. Let it remain for the proper time (two or three minutes), and then lift the glass with the tissue upon it. There is not the slightest difficulty in doing this without being troubled by the appearance of a single bubble.

It is not necessary to remove the paper; it is, in fact, better to leave it on. After exposure, plunge into cold water, and after a few minutes peel off the paper. Finish with water as warm as may be found necessary.—*Philadelphia Photographer.*

\* This is a mistake. Mr. Swan prepares the paper with the pigmented gelatine direct: the paper, in an endless band, being made to pass, by the revolution of the rollers on which it is stretched, repeatedly over the surface of the gelatine preparation.—*Ed. Photo. News.*

## THEORETICAL AND PRACTICAL PHOTOGRAPHY.

BY HOMER FELLOWS.\*

THEORY and practice are two separate and distinct principles, as opposite as the day-dreaming thinker and the busy, bustling workman; and yet they are conjoined, for the workman often alters and adapts the dreams and theories of the thinker, for his own practical purposes, that would otherwise be lost for general benefit.

This philosophical fact is evolved and proved by the consideration of two of the most important subjects that affect the photographic craft at the present time.

There is a wide-spread desire among thinking photographers to class the photographic art with the fine arts, and there is a universal wish to check the depreciation in the value of photographic labour which seems occasionally to overrun us, affrighting the timid and carrying dismay to all. The frequent reference to these two subjects in the columns of the journals is the best proof of their importance; but whether the art can be classed and considered as one of the fine arts by the practical photographer who engages in the business for a livelihood, or will be judged to be a mechanical business, to be carried on by rule and line, as it too frequently is, will probably remain an open subject for debate for some time to come, notwithstanding the frequent expositions that may be made on the subject.

Those who are engaged in photographic work, that ever dwell upon the subject, will probably believe that beauty and grace in position, or softness of shading, is wasted upon the awkward Hibernian whose early education has been much neglected, and unless his hands are posed directly to the front, with no crook nor subsidence in either shoulder, the work will probably be rejected as bad; and the soft shadows, scarcely perceptible, and prized so highly for their delicacy, will be greeted with the remark, "Be jabbers! and my face is not dirty!" On the other hand, customers of taste and judgment may require all the finest display of a man's artistic ability, and bring forth hidden genius as fully as sculpture or painting on canvas; but the photographer who considers all who enter his gallery with money in purse as "grist to his mill," whether Teutonic, Hibernian, or Italian, will find, in the endeavour to satisfy and gratify his customers, that the theory of photography as a fine art will give way to the endeavour to please his customers, and photography as a fine art suffers.

Notwithstanding this, photography is one of the fine arts. From the amateur or photographer who is able to say, "Sit as I place you, and be content," great conceptions of the beauty of the human form and face may be evolved; his own capability will be developed, and the inspirations of genius may be evoked, but it will be at the expense of a photographic business. The business man pleases his customers, the artist pleases himself.

One cannot but envy those whose lot it is to photograph nature in the open fields, among the whispering trees, near the laughing brooks, where beauty may be viewed in manifold aspects, and where they may choose their own with none to gainsay its truth, for God made it. There the artist may luxuriate, feeding his mind, and ever gaining grander and nobler thoughts from the contemplation of the Creator's magnificent handiwork.

But the commercial value of one's work, how shall that be regulated? By what process shall one receive a just compensation for the combined labour of body and mind that is undergone by the photographic art-student? Theory has it that a grand combination may be made of the craft, setting a value upon each and every style of picture made, and thus securing to all that equal proportion of profits which each thinks himself entitled to. But practical experience proves that there are always "black sheep," who wait until prices are regularly established, and then suddenly announce, "Card photographs, \$1.50 per dozen!" "Whole-sized photographs for \$1.00!" to say nothing of these extraordinary persons who offer four, twelve, sixteen, and even fifty gem pictures for twenty-five cents; and thereupon ensues a rush to their galleries, and their neighbours, sick with envy, commence to lower their prices, until it is a hurly-burly scramble who shall make pictures at the lowest figure, without regard to quality or cost. Yet for this who can name a remedy? Human nature will always be

\* *The Philadelphia Photographer.*

the same, and considerations of general welfare will too frequently be sacrificed for the interest of the individual.

An individual photographer may remedy it, as regards his own place of business, by making a regular custom, and not being dependent upon transient trade; certain galleries may deal only in certain styles of pictures, making a speciality of ambrotype, paper, or painted work; but those operators of a middle class, who deal both with the upper and lower strata of society, must make occasional spasmodic efforts to attract public attention, or be left behind by their "black sheep" neighbours before mentioned. But here arises a question for the careful consideration of the craft. May it not be more justly and profitably done—justly for the fraternity and profitably for one's self—than by a wholesale reduction in the price of standard pictures? There are a multitude of old and interesting "dodges," forsaken and forgotten, that, revived, would attract custom without detracting from the character of one gallery. Auto-photographs, double pictures, rose vignettes, the ivory-type, anything dignified with some new name and prepared in some new shape, would, perhaps, prove an advertisement quite as attractive as a lowering in prices of standard work. Ideas may differ as to what constitutes standard work, but the one who imagines that the old or new peculiarity introduced upon his premises is the standard, and consequently condemns all who may infringe upon his prices, will surely be enlightened by time.

The photographic work that, so far, has withstood all assaults, and seems likely to withstand more, is case ambrotypes, card photographs, and frame pictures. To the few who desire gem pictures to be considered as a standard, and long for the old price, "\$1 per dozen," it may be answered that gem ambrotypes can never permanently compete with case ambrotypes, and while albums exist can never supersede card-photographs; consequently they must be classed with the "dodges" as auto-photographs.

What, then, remains for the photographer to make his trade steady is to keep improving in the quality of his work, and not be frightened, nor unduly excited, because of some neighbour falling in the price, and consequently in the quality of his work, and, finding it impossible to continue at that mark, as suddenly rising, and thus presenting the aspect of the weathercock, changing with the wind. Remember, the "race is not always to the swift," and that such men are constantly selling out; and let us not forget that trade is dull—duller than it will be, for the cessation of the war stopped a demand for portraits that was over-inflated, and it is now, consequently, over-depressed. Therefore, grumble not, nor be impatient, but engraft upon the heart the motto, "Time overcometh all things."

## Proceedings of Societies.

### FRENCH PHOTOGRAPHIC SOCIETY.

A MEETING of this Society was held on the 6th ult., under the presidency of M. BALARD.

M. AIME-GIRARD announced the death of M. Leon Focault, one of their most illustrious members, who had been very closely connected with the Society from its commencement, and had, indeed, been one of its founders. M. Girard likewise commented upon the loss sustained by the scientific world generally by the death of Sir David Brewster.

M. DAVANNE stated that the Executive Committee had appointed M. Balard President of the Society, and M. Regnault Honorary President.

M. DE CONSTANT-DELESSERT submitted a positive upon glass in which several objects had been accidentally reproduced in their original colours. It had been obtained by exposing a plate during a very fiery sunset, when the landscape was brilliantly illuminated in gorgeous colours; the picture was under-exposed, and developed with iron and fixed with hyposulphite, but not varnished. It had been kept for three or four months, no particular care being taken to screen it from the light, and when viewed in a flat or oblique position, the original colour of the sky and of the hill slope were found to have been faithfully reproduced. M. Constant says:—

"Some time since I remember having heard of the fact of an American who had obtained natural colours in the camera whilst taking a portrait during an eclipse of the sun, and, on the occurrence of a similar phenomenon at Lausanne about a year

ago, I availed myself of the opportunity of trying the experiment. But, alas! the result was nothing more than an ordinary grey portrait, obtained by an exposure of double the usual period. Nevertheless, being in the possession of the negative which I now submit to the Society, I thought that there certainly might be some truth in the statement of the American photographer, and that he had obtained colours similar to those exhibited in my picture. I leave the question of the phenomenon to those more learned in the matter than myself, although I may mention that some time ago, when occupied with the Daguerreotype process, I several times obtained colour in various parts of the clothing and drapery of my sitters."

M. DAVANNE then communicated a few remarks on dry processes by M. de Constant. That gentleman spoke highly of the gum dry process, and stated that collodionized plates coated with a solution of gum to which a small amount of sugar had been added were found to keep very well, and gave remarkably soft and delicate results; they were likewise very rapid in their action. Plates prepared by M. Baratti's coffee process possessed exceptionally good keeping qualities, and were capable of being preserved in a serviceable condition for two years. M. Constant had likewise experimented a great deal with Bartholomew's morphine process, and was of opinion that although it was not so rapid in its action as the foregoing, still, for photographing objects presenting much contrast of colour, the method possessed a marked advantage. A very long exposure might be given to a negative without any bad effect, and it was only by means of this process that M. Constant was able to obtain a successful reproduction of a picture painted in green and yellow colours.

MM. FORDOS and DAVANNE communicated another note with reference to the destructive action of metallic powders upon photographic positives (see p. 176).

M. DARLOT presented the Society with an apparatus of gutta-percha constructed for the purpose of preserving sensitized collodion plates in a damp condition. The apparatus is so arranged that the plates are quite sheltered from any movement resulting from the motion of the water during the carriage of the machine, and the adherence of the collodion to the glass plate is therefore not interfered with in any way. M. Darlot exhibited a large number of negatives taken by means of the apparatus by General Mongin, to whom is due the credit of having originated it. Some of the plates were not exposed until four, eight, or even ten days after their preparation, and were not developed for several hours, and, in some cases, days, after exposure, which exceeded but little that of wet plates.

M. JEANRENAUD communicated to the Society his mode of operating with Swan's carbon process, and supplemented his remarks by executing, in the presence of the members, several of the essential manipulations connected with the method.

The proceedings then terminated.

### NORTH LONDON PHOTOGRAPHIC ASSOCIATION.

THE usual monthly meeting of this Society was held on Wednesday evening, April 1st, in Myddelton Hall, Mr. W. W. KING in the chair.

The minutes of a former meeting were read and confirmed, and Mr. J. Cruttenden, of Maidstone, was elected a member of the Society.

The proceedings consisted chiefly of general conversation, no paper having been provided for the evening. Mr. Wharton Simpson described a print he had received from Mr. Gaffield, of Boston, illustrating the amount of light transmitted by different samples of glass (see p. 158 in our last). After some conversation on this subject, in which Mr. Goslett, Mr. Boeket, Mr. Shave, Mr. Dunmore, and the Chairman took part, Mr. Dunmore exhibited a fine portrait taken with a concentrated light. After some conversation on the subject, the proceedings terminated.

## Correspondence.

### PHOTOGRAPHY AND ARCHÆOLOGY.

DEAR SIR,—On reading Mr. Henderson's paper on "Photography as an Aid to Archæology," I notice that he alludes to the "labours of Fergusson and Hope in Indian architecture." Mr. Henderson does not seem to be aware that the photographs

(illustrating the work of Messrs. Forgussou and Hope) were taken by Colonel Biggs, R.A.; and, I believe, he received a medal, at the Paris Exhibition, for the pictures in question.—I am, dear sir, yours truly,

A. W. HOSMER.

*Plymouth, April 6th, 1868.*

### KEEPING PROPERTIES OF TANNIN PLATES.

SIR,—As photographers will now be making arrangements for the ensuing season, I send the following particulars, showing the keeping qualities of the plates prepared by the tannin dry process. On the 9th of June, 1866, the plates were prepared: on the 30th March, 1868 (nearly twenty-one months after the plate was prepared), I took the negative, from which a print is sent herewith. The exposure was six minutes and a half; the day clear and bright. The minute particulars on the walls and thatch, the shadow on the dial, and even the stones and glass in the gable of a house on the opposite side of the churchyard, come out as clearly as on a freshly made plate. The experiment has been made also with a stereographic plate, prepared at the same time, and with equal success. The collodion was Ponting's bromo-iodized, newly made; the glasses received no preliminary coating; the bath, that used for his wet collodion; the preservative, 15 grains of tannin and  $\frac{1}{2}$  drachm of methylated spirit to 1 ounce of water; developer, a solution of pyrogallie acid and absolute alcohol, mixed with nitrate of silver, citric acid, and water, at the time of developing. The picture did not start out, but developed gradually; and this is the only difference between this and a freshly made negative. The plates have been kept in a common white wood box with grooves, placed in a drawer in a room in constant use, so that they were kept dry. The lens was one of Grubb's applanatic, two inches diameter.

I have thought it right to trouble you with the above particulars, as they may be important to travellers, showing, as they do, the value of tannin plates to persons on long journeys, or in wild districts, in cases when an instantaneous photograph is not required. I have now used this process for more than six years (the plates I prepare myself), and though it may be slower than others, it is more sure; out of twelve plates I count on eleven negatives with certainty, and generally have the whole dozen.—Yours truly,

G. W. O.

*April 5th, 1868.*

[The print enclosed by our correspondent is clean and bright, showing, perhaps, a trace of under-exposure in lack of detail in deep green foliage and in the dusky non-actinic trunk of a tree. It is a striking illustration of the keeping qualities of the plates.—Ed.]

### CLEANING VARNISHED PLATES.

SIR,—I see in a recent NEWS a method for cleaning old varnished negatives. I have used the following for years with perfect success:—Sulphuric acid (say) three parts, and nitric acid one part; mix in a saucer a small quantity, and apply with a clean rag to the varnished side, then the other side and edges all the plates to be coated; put them in a pan or other earthenware vessel; pile them up one over the other, so as to let the back of one plate come in contact with the face of the other; let them remain a few hours, then cover them with water; let them soak a day or two or more, changing the water a few times to get rid of the acids; rinse thoroughly in a couple of waters, and the plates are perfectly clean. A bucket of water should be provided beforehand, to wash the hands occasionally when coming in contact with the acids.

Acids, after making pyroxyline, will answer the same purpose by immersing the old plates in a dish.—Very respectfully yours,

C. R. LOBB.

*Wadebridge, March 30th, 1868.*

### Talk in the Studio.

SOLAR ENLARGEMENTS ON CANVAS.—A correspondent of the *Philadelphia Photographer* gives the following details by which he states that fine results can be obtained:—"First prepare the

canvas with a very thin solution of negative varnish, then coat it with albumen prepared as follows:—

Albumen	...	...	...	10 ounces
Iodide of potassium	...	...	...	200 grains
Liquid honey...	...	...	...	2 ounces.

Beat to a stiff froth, and let settle; coat the canvas with the above in the following manner:—Pour a small quantity on the whole surface (avoiding bubbles as much as possible), then pour a larger quantity of the albumen on, and float the canvas freely, and let it drain back into the dish. When dry it is ready for use. It is silvered as follows:—Take a solution of plain silver 30 grains strong, acidified with acetic acid 10 drops to the ounce, and flow it over the canvas in the dark; shake lively until the canvas has a smooth, clean look, then print, while wet, deep enough to make the image quite plain. Then develop with a saturated solution of gallic acid; wash well, and fix with soda 2 ounces, water 10 ounces. When fixed, wash thoroughly; and when dry, varnish with a very thin coat of negative varnish, and it is ready for the artist. Although with the above process I have made and sold a great many pictures of that kind, I prefer (and so does every good oil painter) to make a sketch through a carefully made transparent positive. In putting a photograph on canvas by any process, it alters the condition or consistency of the canvas surface so much that it is very difficult to preserve the purity and harmony of colours."

ANOTHER METHOD OF ENLARGING ON CANVAS.—W. M. Gardner also gives the following as an excellent method:—"First prepare the canvas. Rub it with pulverized pumice-stone, then make a paste of China clay and water, and coat it. When dry wash off, and, while wet, pour on a solution of 50 grains of bromide of potassium, 10 grains of water, 5 grains of cyanide of potassium, and set it aside to dry. When dry silver it with a solution of 30 grains of nitrate of silver, 1 ounce of water,  $\frac{1}{2}$  ounce of acetic acid No. 8, and print while wet. Fix in a weak solution of hyposulphite of soda, and it is ready for the artist. This process is for solar camera printing; or, if wanted to print by contact, prepare the canvas the same way. Salt the same as plain paper, and silver it with a 40-grain silver solution, and tone and fix as usual. This process I have used for years, and have not had any fault to find with it."

COLLODION GIVING INTENSITY.—A correspondent writes:—"In August last you gave, in PHOTOGRAPHIC NEWS, formula for iodizing plain collodion, which formula is, I see, repeated in the new YEAR-BOOK, page 78. I have just tried  $7\frac{1}{2}$  ounces of plain collodion which I so iodized about six months ago, and am much pleased with the result; the chief feature being greater resistance to the light in printing, enabling me in some cases to do without any redevelopment. I coated a plate half with the above, and half with an ordinary sample, and the difference in favour of that treated as you recommend is very great."

UTILIZING OLD NEGATIVE BATHS.—The same correspondent says:—"In respect of old baths, I have always used them up by neutralizing with com. soda at a rather high temperature, and boiling down to 60 grains sol. Used for printing, such a bath, with addition of sugar *a la Bovey*, gives very rich tones, of a maroon tint."

INTERNATIONAL COPYRIGHT WITH AMERICA.—We mentioned a few weeks ago that a Bill for International Copyright with this country had been introduced into the House of Representatives, U. S., and expressed a hope that works of fine art would be included. The American correspondent of a daily contemporary says:—"Frightened by the petitions from the friends and opponents of an International Copyright Law, the joint committee on the library has 'come to an informal understanding' to postpone indefinitely action on the Bills already referred from the Senate and House. A long farewell to international copyright!"

OLD BATHS.—A correspondent, Mr. C. R. Lobb, of Wadebridge, sends us the following:—"A simple way of evaporating old negative baths to dryness is to put the evaporating-dish in the kitchen stove on a little sand, open the door every ten or twenty minutes to let out the steam until evaporated to perfect dryness, and let it slowly cool; leave it a few hours, and the silver will part from the basin, and can be removed quite easy. I find the above plan more rapid and much less trouble than the sand-bath. I quite agree with all that has been said: the silver is quite equal, if not superior, to new, for making a bath. The last few days I have been trying the silver for printing

evaporated from old negative baths, and I find it quite equal to new. Sugar added to the printing-bath is a great success; but how long the paper will keep in summer remains to be proved. Probably, in very hot weather, more sugar may be required. I enclose a street view taken with a bath doctored with cyanide evaporated to dryness, and made 35 grains to the ounce, but I do not think a bath treated with cyanide lasts long."

**COL. BURKE'S PHOTOGRAPH.**—An order was made a few days ago upon a photographer to deliver up all portraits and negatives in his possession of a portrait of Col. Burke, which had been published, and the registration at Stationers' Hall was ordered to be cancelled.

**RAPHAEL REPRODUCTIONS.**—The collection of photographs, engravings, &c., of Raphael's works, commenced by the late Prince Consort, has been continued by the Queen. It will ultimately be bound in about 50 or 60 huge volumes, and at the present time a catalogue of the whole collection, which has been compiled by Mr. Roland, formerly librarian to his Royal Highness, and who has had the largest share in the labour of forming it, is being rapidly carried through the press. It is understood that though this work is, in the first instance, intended by Her Majesty for distribution in the way of presents among her personal friends, foreign Sovereigns, and others who have aided in carrying out the Prince's plan, a special edition will afterwards be published for the use of amateurs and Raphael collectors.

**PHOTOGRAPHIC CONVENTION IN AMERICA.**—A national convention of photographers will be held in the United States in course of the present month, to consider many subjects at present affecting the general interests of the profession. The bromide patent, the tax upon photography, the prices of photographs, and various other topics, will be brought under attention, and motions passed with regard to them.

## To Correspondents.

**PHOTOGRAPHER (Derby).**—Streaks on the plate may be due to various causes: floating seum on the surface of the solution, immersion before the collodion is sufficiently set, alkalinity, insufficient iodizing, or excessive strength of the solution will tend to this result. To avoid it, see that there is no floating seum on your bath, that the solution has a slightly acid reaction, and avoid immersing the plate until the film is sufficiently set; also, when there is a tendency to streaks, keep the plate in motion all the time it is in the bath, from the moment of immersion until it is ready for use. 2. Marblings may also arise from various causes, as they are of various kinds. If you will describe specifically those which trouble you, we will endeavour to help you to a remedy. 3. For photographing interiors, double or triple combinations are necessary, as single lenses will give curved lines. A portrait lens may be made to answer very well.

**W. J. A. G.**—Much depends on circumstances. If a very slight increase of intensity is required in the finished negative the use of tincture of iodine, to turn the deposit to an olive tint, is very efficient; but care is necessary in using this, because if its operation is continued too long the colour becomes of a light yellow tint, not at all non-actinic, and the molecular character of the deposit is changed, so that light is easily transmitted, and the negative is made less vigorous than before. The method recommended by Mr. England, in which the varnish is removed by alcohol, and the negative intensified with an alcoholic solution of pyro and silver, gives a little more control over the operations. You will find it described in detail in our YEAR-BOOK for 1867, p. 64. 2. For intensifying before fixing the use of an iron solution with a trace of silver involves the least trouble. For intensifying after fixing pyrogallie acid and silver is, we think, more efficient than an iron solution. 3. Two thicknesses of the black twill you enclose may be safely used, we think, for covering a dark tent.

**C. BURTON.**—Much depends on your skill and experience, as to whether it will be wise for you to attempt to albuminize the paper yourself. It is not a difficult operation; but still, unless you have had some experience, we cannot advise you to rely on your own operations, but should rather recommend you to send the stock of plain paper you have to some one engaged in the business to albuminize for you. If you wish to try, beat up the whites of fresh eggs thoroughly, and add 6 grains of chloride of ammonium to each ounce of albumen solution. Float for half a minute, and hang up the sheets in a room at a temperature of from 70° to 80° Fahr.

**J. B., N.**—If you find the collodion too thin, and the negatives are lacking in vigour, you may, without any impropriety or risk, add

more pyroxyline; we should think at the rate of about 1 grain to each ounce of collodion. But your safest plan will be to experiment on a small quantity (say a couple of ounces) before touching the bulk. If, on trial, this is satisfactory, you can then deal with the whole.

**R. GILL (India).**—We fear that, from some cause, a combination which takes place between the silver and the size in the paper becomes decomposed before the prints are fixed, and an insoluble silver compound remains in the paper, causing the dirty brown, mottled, opaque markings seen on looking through the print. It is difficult, without a more precise history of the case, to indicate accurately the cause of the evil, but we may make some suggestions which, if observed, will probably remove it. See that your albuminized paper is not kept in a damp place, and that it is not used when any indication of decomposition in the albumen is present. Do not use the silver bath too strong, nor float too long: a 40-grain bath, with three ounces of alcohol in each pint of solution. Keep the sensitized paper dry, and print, tone, and fix as soon after the paper is prepared as possible. Use a very strong fresh hypo bath. Try omitting the fuming; we scarcely recommend fuming in a hot climate unless the silver bath contain free nitric acid. If fuming be applied, the paper should be printed, toned, and fixed immediately after. The opaque mottling might be due to imperfect fixation only, but, from the discoloured appearance you describe as being present before fixing, it is evident that some decomposition takes place in the sensitized paper.

**COLLODION.**—The proportion of water present in a toning bath regulates the rapidity of the operation, but beyond that it is not important. Various formulae vary in giving from 2 ounces to 10 ounces of water to a grain of chloride of gold. In very hot weather, when the bath is active, we should probably use 8 or 10 ounces of water; in winter not more than 5 ounces. 2. The process of complete development ought not to require anything like an hour; a quarter of an hour would be a full time. 3. Be so good as to state details of your experiment with the morphine process, so that we may, possibly, point out the cause of failure. 4. The use of a trace of a bromide in alkaline development is to prevent fog, which it does very effectually; too much would retard development.

**R. M. D.**—The mottling and faintness of the print are due to the use of a weak silver bath, or to imperfect contact of the albuminized paper with the solution. Sometimes, when too small a quantity of the silver solution is employed, so as to cover the bottom of the dish imperfectly, such a result will follow.

**J. L.**—The explanation is what we anticipated; but it merely shows how erroneous was the original statement. An intermittent exposure during different parts of an hour is not an hour's exposure, inasmuch as the plate is not exposed during each interval in which the lens is covered. 2. The process of covering the lens during movement of foliage, and uncovering so as to secure the brief intervals of stillness, is not altogether unusual; but it requires great care, and shows most praiseworthy patience. 3. Thanks; but the compilation would not possess sufficient interest for publication.

**READER OF THE NEWS.**—The query in your former letter mentioned sulphate of soda. The accidental addition of phosphate of soda to hyposulphate of soda would, probably, be without any action in fixing, especially if care were taken to keep the fixing bath of full strength. Its precise result is, however, matter which can only be decided by experiment. Phosphate of silver, if formed, is not soluble in hyposulphite of soda. Try the effect in a small experiment before risking many prints. 2. The dog is capital.

**YOUNG PHOTO.**—The forms for registration are one penny each. Our Publisher will obtain some for you if you send him stamps and a stamped and addressed envelope. He will also superintend the registration if you send him the form properly filled up, and the office fee 1s., and 6d., in stamps.

Several correspondents in our next. Owing to the necessity of going to press a day earlier this week, a larger number of correspondents than usual are necessarily left over.

## Photographs Registered.

- Mr. J. COLLINGS, Cardiff,  
Two Photographs of Marquis of Bute.
- Mr. R. CARLYLE, Grassmere,  
Photograph of Port Wordsworth.
- Mr. R. CADE, Ipswich,  
Photograph of J. P. Cobbold, Esq.  
Photograph of R. C. Ransom, Esq.
- Mr. A. CLARKE, High Street, Stourbridge,  
Photograph of Rev. C. H. Craufurd.
- MESSRS. APPLETON, Bradford,  
Lithograph of Rev. C. Garrett.  
Lithograph of Rev. P. McKenzie.  
Lithograph of Rev. J. Rattenbury.
- Mr. E. HARRISON, Newcastle, Staff.,  
Photograph of Bishop Selwyn.

### NEW METHOD OF INTENSIFYING—YELLOW NEGATIVES.

WE have to bring before our readers a new method of intensifying negatives, which has the merits of extreme simplicity and efficiency, and of preserving delicacy whilst adding materially to the printing value of the image. Photographers are familiar with the value of the intensity which is gained by the non-actinic colour of the deposit rather than its thickness. Wherever vigour in the negative has to be secured by piling up the silver forming the image there is a risk of losing delicacy, sometimes by the granular nature of the additional deposit, and sometimes by its tendency to lateral spreading; but where the resistance to light in the dense parts of the image can be increased by a change of colour rather than a material increase of thickness, the delicacy and sharpness of the image as first developed are retained without sensible diminution.

The method we have recently discovered consists in treating the fixed and washed negative with a solution of permanganate of potash, by which its colour is changed from the dusky grey, common to an iron developed negative, to a tint of a brownish yellow or olive by reflected light, and orange by transmitted light. No appreciable thickness or opacity is communicated, but a great increase in the actinic character of the deposit is produced, so that, with a comparatively thin and delicate negative, great vigour is obtained in the prints.

The image is so transparent and delicate, almost resembling, in some instances, orange glass, that our first impression was that no additional deposit was produced on the image, but that the metallic silver of which it was formed was converted into oxide of silver, which, in a fine state of subdivision, gave the non-actinic yellow tint produced by silicate of silver in yellow glass; but, on further examination, we were satisfied that this was not the only change effected. The permanganate of potash, on coming into contact with the silver image, is decomposed and parts with oxygen, which combines with the silver; at the same time binoxide of manganese is precipitated upon the image. It is probable that, following some chemical analogies, a double oxide of silver and manganese is formed, to which the colour of the image, slightly different to that of either oxide alone, is due; but whether this is the case, or the deposit consists of a layer of oxide of silver and a layer of binoxide of manganese superposed upon it, remains to be determined by further examination. The colour of oxide of silver is an olive brown; that of binoxide of manganese, when artificially prepared, a yellowish brown. The colour of the intensified image is slightly different to either, but partaking of both, and varies, of course, according to the extent to which the action is carried.

The best mode of proceeding is to place the fixed and

washed negative in a dish containing a dilute solution of the permanganate, say ten grains or less to an ounce of water. Probably a dipping-bath would answer better still. The rapidity of the operation will depend on the strength of the solution, and may vary from three or four minutes to a quarter of an hour. Pouring the permanganate on to the plate, especially if the solution be strong, is apt to cause stains of unequal action, as the slightest pause in the flow of the solution is apt to produce a line. The first change observed is the change from the red tint of the permanganate solution to the green tint of the manganate, the negative at the same time acquiring a light yellowish brown tint on the surface only. As the change progresses, this tint deepens and passes right through the film, becoming as apparent at the back of the glass as at the front. The change can, of course, be stopped at any point when a sufficiently actinic effect is secured. The intensity increases, in some cases, considerably on drying, but is restored to the condition of the wet negative by varnishing.

Whether this mode of intensifying will supersede other modes in use can only be determined by experience. At present, we offer it simply as an additional power to the photographer, the exact value of which will be decided in practice. The permanency of such negatives is necessarily a question of time; but, reasoning from analogy, we have no reason to doubt it, as binoxide of manganese is one of the most stable bodies with which we are familiar.

### MR. MCLACHLAN'S DISCOVERY.

MR. MCLACHLAN's communication to the London Photographic Society, made on Tuesday night, is a most important one. Partial as the disclosure must necessarily be when made under the disadvantages of a brief verbal statement at the close of a meeting, it contains matter sufficiently startling for attentive consideration.

Opposed to all accepted theory and hitherto ascertained fact, Mr. McLachlan proposes, in working the wet collodion process, to secure alkaline conditions in bath and collodion as the means of securing immunity from streaks, stains, and fog. He proposes to get rid of the most prolific source of pinholes, the accumulation of iodide of silver in a bath, by destroying its capacity to hold iodide of silver in solution. These are two of the leading results which, amongst many others, Mr. McLachlan proposes to secure, and he asks, assuming the facts to be true, and holding him responsible for their truth, are these conditions which it is important to the photographer to be able to secure? We answer that they undoubtedly are. The presence of nitric or other acid in a bath, at present regarded as almost imperative to clean working, must undoubtedly exercise a disturbing influence on the primary reactions intended to take place, in order to form iodide of silver; and a method

of working with certainty of cleanliness in an absolutely neutral or slightly alkaline bath is in itself a power which promises a long train of advantages of which photographers will gladly avail themselves. The immunity from the most fertile source of pinholes, the gradual accumulation of iodide of silver in the bath, is an advantage that does not require affirming.

We just briefly glance, in passing, at two of the features of a system of working in regard to which its author promises, on occasion of fuller explanation, to point out variously ramifying advantages. Our immediate aim is to give as clear a *resumé* as we can, briefly, of the operations already stated.

Mr. McLachlan commences with a denial of a generally accepted proposition, namely, that a pure neutral solution of nitrate of silver is not altered by light. Although not apparently changed by light, he states that after exposure it has acquired new properties. He dissolves nitrate of silver, by preference of a given quality described on another page, at the rate of one ounce in an ounce of distilled water, and exposes it to the action of light; the longer the time and the more sunny the weather the more perfect the result; but at least a month of summer weather is desirable. The proof of new properties acquired is thus made:—To an ounce of the solution, unsunned, add one drop of a solution of caustic potash containing one grain to the ounce; the result will be the production of turbidity from the precipitation of oxide of silver. Now add a drop of the potash-water to the sunned silver solution, and whilst oxide of silver is formed it is at once redissolved. A considerable amount of the potash solution may be added, Mr. McLachlan states, to a thoroughly sunned bath, and the oxide of silver will be redissolved as rapidly as it formed. This capacity for holding oxide of silver in solution, and preventing its precipitation, is the source of cleanliness and freedom from fog in using an alkaline bath.

After sunning the strong silver solution, to 1 ounce of which 1 grain of the potash solution has been added, 2 grains of iodide of potassium dissolved in a few drops of water are added to 10 or 12 drops of the strong silver solution, and the iodide of silver formed is, after washing, added to 1 ounce of the strong silver solution, by which it is, of course, at once dissolved. Pure distilled water to dilute the solution to a strength of 35 grains to the ounce is now added, and this causes no precipitation of iodide of silver, and the bath may be used at once; but in the course of four or five days another singular property acquired by the silver solution is manifested: a sudden precipitation of iodide of silver takes place, and the solution, according to Mr. McLachlan, has lost the power of dissolving or precipitating any more of this salt. No addition of water produces turbidity or causes further precipitate of iodide; and, in the course of use, no further accumulation apparently takes place, or, at least, no manifestation of its presence in the shape of pinholes.

Then a suitable collodion is required, for Mr. McLachlan lays great stress on the importance of harmonious relation of the various chemicals. At a future time he will explain the manufacture of suitable collodion; but for the present explains the doctoring of a commercial sample. Take a good commercial sample of a certain type—Mawson's is selected as the illustration—in a red acid condition, such as ordinarily secures brilliant and clean negatives. A plate coated with this, and immersed in this alkaline bath, will give inevitable streaks, brain-markings, and other troubles. To get rid of these the collodion must be made neutral by adding a few drops of the potash solution, and, after this treatment, the neutral collodion in the alkaline bath will give a clean brilliant negative—delicate, harmonious, and well modelled, with a shorter exposure than is obtained by the usual mode of working.

For a special mode of preparing the developer, we refer the reader to the report of Mr. McLachlan's remarks on another page, and for fuller elucidation of his system of working they must await his further communication.

It is probable that Mr. McLachlan might have done himself and his method more justice by a written communication, as nothing enforces precision and the absence of redundancy more certainly than the necessity of writing. As the matter stands, he has afforded sufficient information to excite expectation and stimulate experiment, after which a fuller written paper will be received with greater interest and fuller appreciation.

#### MR. WOODBURY'S PHOTO-RELIEF PROCESS.

WHEN an important discovery is made it is scarcely surprising that many claimants for the honour and possible profits of its paternity should start up, as the vanity, cupidity, and capacity for self-deception which exist in the world are prolific parents of such claims. But it is not a little surprising to find, in addition to these, other claimants perversely created by the carelessness or misapprehensions of the recognized recorders of progress in the periodical press. We are not aware, for instance, that M. Braun has ever claimed for himself the discovery of Mr. Swan's carbon process; but we have had very repeatedly to point out for correction erroneous claims made for him by journals which ought to have been better informed.

A similar error is made in the April number of our excellent monthly contemporary, the *Art Journal*, in which an article is devoted to the description of a method of printing, headed "M. Disderi's Patent." The process is really that well known to photographers as Mr. Woodbury's photo-relief process, an example of which was placed before our readers a couple of years ago, the English patent of which was recently sold by Mr. Woodbury to a company, of which M. Disderi is managing director. The process is mentioned, however, throughout as "M. Disderi's method," and only by a passing allusion at the end of the article is any recognition made of the actual originator of this mode of printing. "The peculiarity on which the patent is based is the invention of Mr. Walter Woodbury," it is stated, and the conclusion to which the whole article points, and which, if it be not contradicted, it may be hereafter quoted to prove, is that M. Disderi has patented a new process based upon the relief process of Mr. Woodbury. The simple fact is, that the process which has been put into operation with so much energy and success by M. Disderi is that which has been worked out in its minutest details to its present state of perfection solely by Mr. Woodbury, and the origin of which has never been claimed by M. Disderi.

We have pleasure in noting here that the commercial working out of the process under M. Disderi's superintendence at the establishment at Brompton appears to progress very successfully. The minor difficulties attendant upon working out, on a large scale, a mode of printing based upon new principles and involving many new conditions have gradually disappeared, and excellent pictures on glass and paper are now regularly produced, whilst the sales and orders are already in excess of the supply.

Mr. Woodbury, who has recently been on a business tour on the Continent, has made arrangements which will speedily introduce his process into Italy, and also established negotiations which will probably be speedily followed by its introduction into Austria and Bavaria. The enterprising firm of Goupil and Co., so well known in connection with the extensive publication of engravings and of photographic art reproductions, are rapidly making arrangements for working the French patent on a large scale; and Mr. Woodbury shortly leaves for the United States to take the proper steps for initiating commercial operations with the process under the auspices of a powerful company in America.

#### A MAN'S PROPERTY IN HIS OWN PORTRAIT.

A few years ago an American paper contained an advertisement from a murderer under sentence of death, warning the public that a certain photograph of him, recently published,

was not issued by his authority or consent, and advising intending purchasers to wait a few days for the issue of a new portrait, which, he remarks, will be "taken with my clothes on at the time when the deed was done." A case recently brought before a Judge in chambers reminds us of this case. It appears that a photograph had been taken of the Fenian Colonel Burke in Clerkenwell prison, for the purpose of identification, as the custom now commonly obtains in prisons. When first asked to sit he objected, apparently on the ground that its publication might lessen the value of a portrait which he had already assigned to Mr. O'Halloran as part consideration for his bearing certain legal expenses for him. On being assured that the prison portrait would not be published, he consented to sit, and a negative was obtained. By some indirect practice it appears the negative was reproduced by a Mr. Turner, and the portrait announced for sale in a sensation placard as being the only authentic portrait, and having been taken by command. Application was made by Mr. Merriman, on behalf of Col. Burke, to forbid the publication of these portraits, and the facts having been sworn to, a rule nisi was granted.

On subsequently coming before the Judge a decision was obtained in favour of the application. As the case possesses some interest, we give such detail of the proceedings as we find in the daily papers reporting the case. At the second hearing,

Mr. Merriman (for Col. Burke) said that as there could, he presumed, be no answer to the case stated in his affidavits, he should content himself by referring to them, and to the statutes 24th and 25th Victoria, cap. 73, sections 1 and 7, and 5th and 6th Victoria, cap. 45, section 14, and to await the answer of his friend Mr. Shaw.

Mr. Shaw (for Mr. Turner) said that he must admit his client was entirely in the wrong, but that he had been misled by Captain Codd, the governor of the Clerkenwell prison. Mr. Turner was willing to deliver up the negative and all the copies in his possession, and to pay over to Mr. Merriman's client every farthing he had received from the sale of the photographs; but that he hoped his lordship would limit the amount of costs, and would stay all further proceedings against his client.

Mr. Justice Willes (addressing Mr. Merriman).—What do you say? It appears that Mr. Turner is willing to do everything that is right on his part.

Mr. Merriman said he had no objection to an order on the terms asked for by Mr. Shaw, if his lordship thought he could make such an order. The offence under the statute was a misdemeanor, and as to the question of costs he left himself in the hands of the learned Judge.

After some further remarks on either side,

Mr. Justice Willes made an order expunging the photographer's entry at Stationers' Hall; that all further proceedings of every kind should be stayed upon the delivery up of the negative and the printed copies, and payment of the amount received for the sale of the pictures, to the satisfaction of the applicant, and two guineas costs.

There appears to be some mistake in the report as to the statutes referred to by Mr. Merriman. The statute 24th and 25th Victoria, cap. 73, is a brief Act referring to copyright in designs, and does not contain seven sections. The reference here intended is doubtless to the Fine Art Copyright Act, 25th and 26th Victoria, cap. 68. In this, the first section defines the conditions under which a copyright can be obtained in a photograph; and the seventh section forbids the fraudulent description of, or assumption of, copyright in any work of fine art. The other statute referred to, 5th and 6th Victoria, cap. 45, section 14, enacts that any person feeling himself aggrieved by any false entry in the book of registry at Stationers' Hall shall be at liberty to apply to a court of law to have such entry expunged, which, it will be noted, was done in this instance.

The publication of a portrait without permission is not a thing likely to be of common occurrence, because, both as a matter of good feeling and policy, few photographers would so far disregard the wishes of a sitter; but the question of the legal right to publish a portrait without the consent, or in defiance of the wish, of the original, has not before, that we remember, been the subject of a decision in an English court. The question was recently raised in France by Alexander

Dumas, when his portrait and that of Miss Menken were issued in one group; but in that case the decision was adverse to the applicant and in favour of the photographer.

### COPYRIGHT AND PIRACY.

We reproduce, in another page, an interesting *resumé* of the facts as they stand in relation to the law of fine art copyright, especially in its relation to photographic piracy. Our contemporary, the *Stationer*, in this article, deals leniently and tenderly with the photographic copyist and the vender of photographic copies, believing that ignorance rather than dishonesty accounts for the circulation of piracies in a large number of cases; and further believing that print publishers are themselves guilty, not simply of great folly, but also of moral wrong, in not satisfying the craving of the public for cheap copies of works of fine art, and in omitting to issue details of those goods in which they claim copyright.

We have already often expressed our conviction of the impolicy of print publishers in not issuing small photographic copies of their own works, and so driving piracy out of the field by rendering it unremunerative. The risk of piracy can only be compensated by large sale or large profits, both of which would be reduced by the competition of authorized photographic copies of copyright works. The fact that the issue of photographic copies pays the pirate sufficiently to cover the risk he runs is a guarantee that it would pay the print publisher, who would run no risk. The plea that the sale of the engravings themselves would be injured by the issue of small photographs would not be sustained, we feel assured, in practice. It is rather probable that issue of small copies of a good picture would serve as an advertisement, and extend rather than diminish the sale of the engraving. The charge of moral wrong in not supplying a public want will be, however, indignantly repudiated, it is probable, by the print publishers. So long as they believe that they would sustain personal loss they will naturally ask why they, as traders, should make sacrifices for the public good.

But the suggestion of our contemporary that owners of copyrights ought to make it clear to any one concerned in what pictures they claim copyright is a most important and reasonable one. It ought to be possible to ascertain what is copyright and what is not. At the present moment no such possibility exists. Even the arduous task of searching the registry at Stationers' Hall would fail to afford any satisfactory information, inasmuch as no copy of the design or picture is preserved there. After spending many hours in the search for a special entry it will be found to contain only a vague description of the subject in which copyright is claimed. Take an example from a class with which we are familiar. It is desired to ascertain if a certain portrait of Mr. Disraeli, photographed by Mr. Smith, is copyright; and at length an entry is found running thus,—“Portrait of Right Hon. B. Disraeli, full face, standing position, arms folded;” the due particulars of Mr. Smith's ownership being appended. But it may happen that half-a-dozen portraits of Mr. Disraeli may have been issued by Mr. Smith, every one of which answer to the general description in question; and who shall say to which of them it was intended to apply at the time of entry, or which of them is protected by the registration?

To this it may be replied, that the difficulty in finding an owner for anything affords no excuse for stealing it; that there is a property morally, if not legally, in all designs, and that the facility for copying and appropriating the ideas of another without legal risk should not be made too easy. There is a certain amount of force in this argument, but it is only of very limited application. There exist many engravings of which the copyrights have lapsed by time or neglect, and many copyrights of which no steps were taken to secure. The reproduction and publication of these as

photographic scraps would afford legitimate employment to many photographers, and their distribution would afford pleasure and profit to many thousands of the public. But the conscientious photographer feels himself placed in constant difficulty and danger for lack of certain information as to what he may or may not reproduce with impunity, and without infringing the rights of others. The suggestion of our contemporary to establish a museum of art in which shall be preserved photographs of all works in which copyright exists, readily accessible to the public or those concerned, is, we think, a most useful one, and well worthy the attention of all interested in the maintenance of copyrights on the one hand, and in photographic reproduction on the other. We hope that this part of the question will not be overlooked in the introduction to Parliament of a new Copyright Bill, which is, we understand, contemplated at the first convenient opportunity.

### VISITS TO NOTEWORTHY STUDIOS.

#### MR. ENGLAND'S ESTABLISHMENT AT NOTTING HILL.

WE shall not ask our readers to follow Mr. England to any of the grand studios wherein his magnificent negatives have been produced and his triumphs won: it is not to Niagara, or the streets of Paris, or up the Rhine, or to the peaks and passes of the Alps, which have for years past served as his theatre of operations, with mountain and waterfall, pine forest or rocky glen, for his models, that we now direct the attention of our readers. Our present purpose is to give a brief sketch of one of the most complete establishments we know for printing, and, indeed, all operations connected with photography except portraiture.

The primary purpose of the Notting Hill establishment is printing, and to that end the arrangements are chiefly directed. The most noticeable feature is the large and conveniently arranged printing space under glass. This consists of something like a large glass house, with an area of about 1,300 superficial feet. All round this space are arranged racks or tables, capable of holding from 700 to 1,000 printing-frames, the racks being provided with an arrangement whereby they may be placed at an inclination so as to place each frame at right angles with the sun when it is desirable to print in direct sunlight. The roof consists of a series of sliding skylights, which afford a covering in wet weather, but which are easily moved, so as to bring the printing-frames under the light of the open sky when required. The stands or racks upon which the printing-frames are arranged move on castors, and are readily wheeled into the open air or under cover, into sunlight or shade, as may be required.

A capital arrangement for producing a graduated tint for skies is employed, in order to get rid of the unpleasant mass of white paper which surmounts the landscape printed from a negative taken on a bright cloudless day. It consists of a series of horizontal grooves, the upper half of which is a piece of zinc or tinned iron, curved upwards so as to form a gradually widening aperture, something like this—

The print is placed in the groove so as to protect the portion of the image already printed, the sky portion being exposed to the light in degree regulated by the curved cover, and receives a graduated tint which diminishes greatly as it approaches the horizon of the landscape. As white skies are to Mr. England an abomination, and as it would be almost impossible to print a graduated tint on the large scale necessary, if every impression required carefully shading by hand, in the manner generally adopted, this arrangement for securing a graduated tint is found very valuable.

On examining the frames exposed, we notice that a large number of the negatives have been manipulated in various ways to increase the pictorial effect of the prints, and we learn that Mr. England does not consider it any enormity

to improve his negatives by any of the various methods which experience or ingenuity may suggest as giving value to the final result. Where a portion of the landscape prints through too rapidly, and so buries detail in the print, it is covered with a piece of tracing-paper, the edge of which is serrated so as not to make a hard line, and by printing in diffused light the production of an apparent line or edge is avoided. Sometimes the whole landscape is covered in this way, leaving the sky uncovered, that it may print through a little more perfectly than it could do if the other portion were not thus masked. Sometimes the sky is covered and the foreground uncovered; sometimes merely a piece of very deep foliage is thus protected; but in all cases, with judgment and care, and properly used, this delicate masking is found of great value in securing harmony in the picture.

A large number of the negatives we saw in the course of printing had very effective clouds introduced into the skies, by a method which may prove useful to many of our readers. Mr. England has found the black-lead pencil retouching upon negatives, described some time ago in our pages, very useful for many purposes; but for strengthening clouds already indicated, or introducing them when none are visible, black-lead in the shape of powder is found most useful. This is applied with a stump, after the manner of crayon drawing, by which soft graduated edges to the clouds can be produced. The stumps used by Mr. England, and which seem most efficient, are made by tying pieces of sheet india-rubber over the end of a stick, stuffing with a little of something soft if necessary. The bite of the india-rubber makes the process of graduating the black-lead comparatively easy and simple. The negatives which have received this treatment are chiefly those by the modified collodio-albumen process, the hard surface of the film affording ready facility for the application of the black-lead, which is protected from further rubbing by the varnish which is applied afterwards.

A characteristic feature of Mr. England's establishment is found in the fact that every possible operation connected with the production of photographs is conducted on the premises. Collodion, albuminized paper, nitrate of silver, chloride of gold, &c., are all prepared in the establishment. A carpenter's shop, fully equipped, furnishes facilities for making or modifying much of the apparatus. A very excellent furnace is employed to reduce all the residues and furnish the pure metals for preparing the salts of silver and gold required.

We have before described Mr. England's albuminized paper; suffice it to say now that the formulæ we stated some years ago is in use now. To each ounce of pure white of egg 5 grains of chloride of barium and 5 grains of chloride of ammonium are added, and the paper so prepared is found to give uniformly rich and brilliant prints. It should be noted that as the chloride of barium employed only contains half as much chlorine as the ammonium salt, the 10 grains of chloride employed are about equivalent to 7½ grains of chloride of ammonium. The paper so prepared is excited on a 40-grain silver bath, in which, to every pint of water, 3 ounces of methylated spirit is added, which arrests discolouration of the bath and of the prepared paper.

The paper is sensitized in whole sheets, about fifty of which are printed every day in cabinet or stereo pictures. The system of toning adopted has been employed without variation for many years, and is found to give excellent and certain results, either of a warm tint or a deep neutral black. Half an ounce of a saturated solution of bicarbonate of soda is added to 15 grains of chloride of gold and about three pints of water, the solution being used about an hour after it is mixed. As bicarbonate of soda is sparingly soluble, a saturated solution containing about 10 grains to the ounce, it will be seen that the toning bath is scarcely alkaline, containing not more than one-third of a grain of carbonate of soda to each grain of chloride of gold; a proportion just sufficient to decompose the chloride and set up toning action without producing an alkaline condition.

The washing arrangements are very excellent. After the fixed prints have received three or four rapid changes of water to remove the bulk of the hypo, they are transferred to the washing machine, an invention of Mr. England, and used by him for the past ten years, diagram of which we give. It

consists primarily of a large trough 7 feet long, by 4 feet 6 inches wide, and 11 inches deep. Placed in this are two trays with lattice work, made of gutta-percha strips, at the bottom. Just above, supported by a bracket on the wall, is a box containing a water-wheel turned by the stream from a tap just above it. The two trays are connected with this wheel by a rod attached to a crank, and as the wheel revolves the trays are kept in a constantly oscillating motion, which serves the double purpose of preventing the prints from sticking together, and of securing more effectual washing than is effected by great soaking. The water which turns the wheel passes through a pipe at the bottom of the wheel-box into the washing trays; and about once in every hour, the large trough having become full, brings into action a syphon, which empties it in ten minutes, leaving the prints to drain for a time, resting on the gutta-percha lattice work. The washing, thus managed, is found to be very effectual. The prints are removed each morning after a night's washing, and placed in a straight heap in a screw press, by which all the water is squeezed out of them, which is a more effectual aid to drying than blotting off; and when spread on canvas frames the prints rapidly dry flat and even, with little curling or cockling.

It is not necessary here to describe the complete and efficient means of saving and reducing the residues and waste, nor to enter into the details of mounting, printing the mounts, &c., beyond mentioning, in passing, that for the mounting a thick fresh solution of gum arabic is preferred to paste, glue, or india-rubber.

We find in the course of conversation that the modification of the collodio-albumen process, by which all the plates for last summer's campaign were prepared, was so far successful that Mr. England will employ it again this summer with even more hope than before. The negatives produced by it, we find, on examination, are singularly like those produced by the wet process, possessing even a trace more softness, delicacy, and detail than Mr. England's usual wet collodion work. They are also, singularly unlike most dry-plate negatives, free from abnormal deposit or fog of any kind, here and there a little bare glass in the deepest shadows giving the images a good deal of positive character. Some of them, we learn, which had been a trifle under-exposed, had the usual plan of development supplemented by the aid of ammonia. One negative, which, after developing some time, appeared hopelessly under-exposed, scarcely any trace of an image appearing, was finally washed, dried, and put away in a plate-box until after his return to England, when it was subjected to alkaline development, and finally yielded a capital negative without any appearance of having been forced in development in any way.

Mr. England's travelling equipment for the wet process

is one of the most convenient we have seen. The knapsack tent, made from his own design, is light and commodious; but, although it accompanied him, to be ready in case of emergency during last summer's tour, it was never used, the dry plates never having failed. These were prepared at various places *en route*, some convenient place being selected every now and then to serve as head-quarters for a few weeks, from whence to ramble for a few days, and return to develop the negatives obtained, and prepare more plates. As a rule the plates were developed within a few days of their preparation, but in some cases as much as a month elapsed between the operations.

Mr. England is one of the very few veterans of the art who commenced the practical business of life as a professional photographer. Upwards of twenty years ago, when he was a lad of eighteen years old, he undertook the charge of a Daguerreotype portrait establishment. For many years he has been chiefly devoted, however, to the production of landscapes, especially stereoscopic and instantaneous work. His success in these departments has been most unequivocal, his especial work being unsurpassed by any in the world, and equalled by very few. His views of Niagara, taken under serious disadvantages, upwards of ten years ago, are still the finest views of the grand scenery of the Falls that have been issued. His instantaneous views of the streets of Paris have never been surpassed. His views of the International Exhibition of 1862 were perfect, and, by contrast, give a singular point to the failure in the attempt to photograph the recent exhibition of a similar kind. The Swiss scenery, which for some years has absorbed Mr. England's attention, is executed with a degree of care which leaves nothing to desire. Perhaps the most distinguishing characteristic in all Mr. England's operations is their pre-eminently practical quality. An earnest experimentalist, with a perfect knowledge of all the capabilities of the art, and a liberal communicator of all the results of his knowledge to his brethren, it is well known to all those who have the advantage of Mr. England's friendship, that when he advises a given course, or when he publishes a process, it is certain to be practical and trustworthy. A cultivated artistic feeling characterizes all his pictures; whilst their photographic manipulation is generally absolutely perfect. A scrupulous and conscientious care to secure in all cases the best possible result is manifest. His equipment of lenses to one camera, and for size of picture, includes about a score of Single, Triple, Wide-Angle, and Rectilinear lenses, varying from three inches to fourteen inches in focus, so that every subject may receive such treatment as shall produce absolutely the best result.

Mr. England is one of the few who have already introduced photography to a second generation: his eldest son, a youth of seventeen, has commenced his career as photographer, as a dry plate man, having produced some excellent dry plate negatives, before he has yet produced one by the wet process.

#### PICTORIAL EFFECT IN PHOTOGRAPHY; BEING LESSONS IN COMPOSITION AND CHIAROSCURA FOR PHOTOGRAPHERS. BY H. P. ROBINSON.

##### CHAPTER XII.

"Nothing is more strange in art than the way that chance and materials seem to favour you, *when once you have thoroughly conquered them*. Make yourself quite independent of chance, get your result in spite of it, and from that day forward all things will somehow fall as you would have them," — *Ruskin*.

"It is often said: Study nature; but nature does not compose; her beautiful arrangements are accidental combinations, and none but an educated eye can discover why they are so. Nature docs, and ought to, supply the materials for fine pictures; but to select and reject, to adapt the individual parts to the production of a perfect whole, is the work of the artist, and this it is that stamps the emanations of genius." — *Burnett*.

##### THE SKY—continued.

The doctrine lately set forth by the matter-of-fact school concerning the impropriety of using any other sky in a pho-

tograph—or, indeed, as it must naturally follow, in any other picture—than that which was actually presented at the moment of taking the rest of the picture, although of so little importance as to be scarcely worthy of notice, yet demands a few words, as it may have a detrimental effect on the unthinking, or those whose faith is not quite confirmed in photography as an art.

That this doctrine is utterly wrong—a pestilent error, without even a figment of truth to support it—is capable of easy demonstration. It is, indeed, so absurd that the wonder is it should have ever found its way to the light. It would be quite beside my present purpose, or beyond the scope of these articles, to enter into any elaborate discussion upon the point; but it will be enough to remind the student that if the idea be carried out in the manner advocated by the school above-mentioned, it comes to this: any landscape is equally beautiful at all times, and, notwithstanding it may be seen under various aspects, a photograph of it, if absolutely accurate, will, in virtue of its accuracy, be a work of the highest art; so that art becomes no more than a mere servile copying of nature, without even the slightest reference to the aspect under which nature is seen. Can art be thus brought down by men of no minds to such a level? Certainly not. The highest aim of art is to render nature, not only with the greatest truth, but in its most pleasing aspect; to show forth the storm in its grandeur, or to gladden the eye with the smile of nature's light. Truth may be obtained without art. The exact representation of unselected nature is truth. The same of well-selected nature is truth and beauty. The former is not art, the latter is.

I do not shrink from the statement, although Ruskin may be quoted against me, that the highest duty of man is the cultivation and improvement of God's works, and by doing so he cultivates himself.

As an instance of the improvement of the works of nature by man, going on every day, I ask, what is education but the improvement of nature? I once heard an eloquent speaker refer to education as the attainment of the highest truth. Pointing to a rough-hewn block of wood or marble, he said that was natural truth; but polish the rough-hewn surface, and all the delicate grain or markings, the varied veins and gradations before unseen, were now brought out, and a thing of beauty was discovered, which was still higher truth. If we were—following the doctrines of the leave-nature-alone teachers—to abstain from secluding our children to school, what sort of savages would they become! Yet that would be leaving nature to herself. Why, it has been the instinct of mankind from the earliest ages—from the time our ancestors painted themselves blue because clothes were scarce—to improve nature. We may be too highly civilized, but a "state of nature" would scarcely be allowed now-a-days, but would soon attract the attention of the police. On the contrary, the endeavour of mankind is, as it should be, to apply that to nature's greatest work which is calculated—

"Not only to keep down the base in man,  
But teach high thought, and amiable words,  
And courtliness, and the desire of fame,  
And love of truth, and all that makes a man."

But, to return to our immediate purpose, there is comfort for the artist photographer, not only in the quotation from Ruskin, at the head of this chapter, which entirely neutralizes any extract from the same writer to the effect that nature must be slavishly imitated, whether that nature be a pig-stye or a palace, so that it should *chance* to come before the artist, but in the fact that Turner, who in the opinion of that writer and many others could do nothing artistically wrong, or depart in any way from nature, not only improved nature by twisting his views out of all resemblance to the localities they were intended to represent, but actually studied many of his best skies from the end of Margate jetty, and afterwards fitted them to any picture he thought they would suit.

I may here quote an anecdote related by Burnett of Turner which is applicable here:—"Driving down to his house

[Woodburn's] at Hendon, a beautiful sunset burst forth; Turner asked to stop the carriage, and remained a long time in silent contemplation. Some weeks afterwards, when Woodburn called upon him in Queen Anne Street, he saw this identical sky in his gallery, and wished to have a landscape added to it; Turner refused the commission—he would not part with it. Wilkie used to call these studies 'his stock-in-trade.' His skies look like transcripts of nature, but they are the result and remembrances of his contemplation. They are composed of many combinations and changes in the heavens, drawn from the retentive stores of his memory; they are adapted to the picture in hand by the different qualities required. If the subject is indifferent, he trusts to the richness and composition of the sky to give it interest; and if the scene is complicated, and consists of many parts, he makes use of the sky as the seat of repose."

It must be remembered that nature is not all alike equally beautiful, but it is the artist's part to represent it in the most beautiful manner possible; so that, instead of its being death to the artist to make pictures which shall be admired by all who see them, it is the very life and whole duty of an artist "to keep down what is base" in his work, to support its weak parts, and, in these parts, which are subject to constant changes of aspect, to select those particular moments for the representation of the subject when it shall be seen to its greatest possible advantage.

I have not in this article advocated the use of artificial skies, or painting in skies on the negative, although I believe in the legitimacy of either method, and it is the constant practice of our best landscape photographers—Bedford, England, Mudd: need I mention more?—to improve their negatives in the sky and other parts with the brush. I have not done so, because I believe the natural sky, added from a separate negative, to give the most complete results; but I see no reason whatever why the negative should not be improved, if it is found necessary, without any departure from truth.

Before photography was discovered, artists used to paint skies to their pictures; indeed they then, as now, painted their whole pictures; but now that photography has asserted its claim to mechanical accuracy in its transcripts of nature, there has sprung up with it a class of men who would have us believe that to touch a photograph with a paint-brush is almost the greatest sin a man can commit, and they would hardly shrink from even taxing a man with immorality and want of religious principle who, having taken a good photograph, should, by a few strokes of the pencil, judiciously applied, make it, as well as a good photograph, a good picture.

In conclusion, I cannot refrain from quoting part of a letter on the sky in the PHOTOGRAPHIC NEWS, September 22nd, 1865, by an admirable writer, who, under the *nom-de-plume* of "Respite Finem," favours us too seldom with his views on our art; after which let us turn from these vain janglers to the consideration of something more profitable.

"The clouds have to play a far more important part in photographic landscapes than they have yet done. I do not say that a photograph without a sky, or with a mass of white for the sky, is altogether unnatural, but, to me, it is very tame, insipid, and unpoetical. How a photographer with a conception of the enormous resources he possesses in the clouds can ever neglect them in his landscapes I cannot understand. They have such a varied beauty in themselves; they give to the artist such a command in balancing and harmonizing his composition; if well managed, they so assist everything else in taking its place, that I cannot understand their frequent neglect by the photographer. One reason is, I know, the difficulty of securing them in the same negative as the foreground. If I am right in my former letter on the legitimacy of combination in photography, then there should not be a second opinion as to the propriety of using a second negative, looking to it, however, that the clouds harmonize with the picture and involve no impossibility or practical solecism. To avoid this a careful and

constant study of nature, as well as art, will be necessary. Heed not, I would say to the photographer, the thoughtless objector, or bogus critic, who tells you that the landscape can only harmonize with that sky with which it was illumined when you obtained your negative. Remember that the portion of the sky which produces lights or shadows on your landscape is rarely that which the eye sees in looking at that landscape. How far this is true you will ascertain by the study of nature; and of all the studies of beauty known to man, there is none so grand, so lofty, and so varied as the study of the aspects of the sky and the glories of the clouds. And when, with Ruskin, you have gazed on a glorious sunset, 'through its purple lines of lifted cloud, casting a new glory on every wreath as it passes by, until the whole heaven, one scarlet canopy, is interwoven with a roof of waving flame, and tossing vault beyond vault, as with the drifted wings of many companies of angels; and then, when you can look no more for gladness, and when you are bowed down with fear and love of the Maker and Doer of this, tell me who has best delivered his message unto men.'

#### JOTTINGS ABOUT PHOTOGRAPHIC COPYRIGHTS.\*

The numerous prosecutions lately instituted by Mr. Graves against dealers in photographic scraps, &c., have caused much attention to be given to the subject. We have, therefore, collected a few jottings pertinent thereto, believing that they will be perused with interest.

In 1735 William Hogarth obtained an Act of Parliament (8 Geo. II., c. 13) which gave him copyright in his original engravings for fourteen years from their first issue. Infringement of the copyright subjected the infringer to a fine of five shillings for every copy possessed, and forfeiture of the piratical plate. The penalties were, however, to be sued for within three months. As this Act only afforded protection when the designer and publisher was the same person, it was inoperative when one person designed, or engraved, and another published. To remedy this defect another Act was passed in 1767 (7 Geo. III., c. 38), which extended the copyright to printsellers or others who should employ designers to work for them. It also enlarged the period of copyright to twenty-eight years, and permitted the penalties to be enforced within six months after the commission of the offence. This Act, however, omitted to include those persons who should illegally sell, or expose for sale, any pirated copies; and a similar omission was made in a subsequent Act (17 Geo. III., c. 57) passed in 1777, the effect of which was exemplified so recently as November 9th, 1862, when Mr. Currie, at the Bow Street Police Court, decided that Mr. Sydney Powell, who appeared at the suit of Mr. Gambart, had not, by selling copies of Rosa Bonheur's celebrated painting of "The Horse Fair," infringed the Act. In 1836 the provision of the previous Acts were extended to Ireland, and in 1852 to French prints published in this country; but such prints must be registered at Stationers' Hall within three months after their first publication in France. By the Act (25 and 26 Vict. c. 68) which came into force on the 29th of July, 1862, a copyright was given to artists and their assignees for the life of the author, and for seven years after his decease, in all paintings, drawings, and photographs, first produced after the enforcement of the Act. By a strange omission, however, engravings are not mentioned, though there can be no doubt that it was intended by the legislature to include them. Still, however, dealers should use care, as engravings may be, and most probably have been, photographed, and the photographs registered at Stationers' Hall, as was done by Mr. Gambart before he published his print of "The Derby Day."

Considering the difficulty, therefore, that exists in discovering what is copyright and what is not, it appears surprising that the retail tradesmen did not better support a "Protection Society," that was some time since especially established for their behoof, particularly as one of the principal objects of the association was to keep its subscribers "posted up" in all the doings of their trade.

For our own part we believe that print publishers do not sustain pecuniary loss by the reproductions in large numbers

of small photographed copies of their works; while we opine if they would themselves publish such series, a large sale and corresponding profits would accrue. And a similar view of the case is taken by the *Athenæum*, than which there has not been a greater advocate of the rights of authors in both literature and the fine arts. Our contemporary on this subject says:—

There appears to be strong grounds for believing that if judiciously used such photographs would give great publicity to and largely increase the sale of engravings, when the prevailing false and vicious system as to *proofs* has been abandoned, and the print-selling trade put upon a true and sound basis. If every publisher were to publish a complete set of small photographs of all his engravings, including all the title and other inscriptions, they would not only operate as the best possible advertisements of the engravings, but likewise do more than anything else to prevent the mischief now complained of. The publisher would not merely be able to undersell the alleged pirates, but also effectually stop their sale: for what tradesman would be insane enough to purchase spurious copies with the chance of exposing himself to legal proceedings, when he could escape that danger by only dealing in authorised copies obtained directly from the publisher or his agents? If it be objected on the part of the publishers, that spurious copies of photographs may be easily and inexpensively reproduced, the answer is that the judicious use of a *trade mark*, which may be of any size, will materially contribute to protect the property in copyright photographs as well as in engravings.

There are, of course, two sides to every question, and in answer to the foregoing hypothesis the print-publishers say they know from experience that cheap issues materially injure the sales of the originals, in proof of which Mr. Gambart asserted in 1862 that "The Horse Fair" and "The Light of the World," which had at one time realized £1,000 each per annum, were not at that time producing a tithe of the amount, a result, he assumed, that had its rise in the number of pirated copies that had been issued. The publishers also affirm that they have no right to diminish by acts of their own the value of the engravings they have disposed of. And further, that collectors who pay large prices for choice engravings do not care to see copies sold at one-hundredth part of the published price. They also argue that if prints were to be issued at one guinea instead of from five to fifteen guineas, a sufficiently large number of good impressions could not be struck off; and, that as framing a large engraving costs from four to eight guineas, the price would still be beyond the means of the major portion of the middle classes. There is yet another class of pirates that the publishers claim to be much injured by, but against whose practices they have no redress; viz., amateur photographers, who get possession of an engraving, copy it, and, for the mere purpose of showing their skill, present copies of the work to their friends, who are possibly persons of means, and well able to purchase the original prints. Again, they state that pirated photographs are rapidly ruining the line engravers, who cannot now find sufficient employment. At one period popular plates were engraved and re-engraved according to the demand, but since the advent of photography the cost of once engraving barely remunerates the publisher.

There is undoubtedly some truth in what the copyright owners say, though we do not give credence to all their pleas; and while they are so remarkably averse to the doings of piratical photographers, they are not ashamed to impose upon the public a number of what they term "proof" impressions. In fact, instances are known where the number of *proofs* has considerably exceeded that of the published impressions. Such a circumstance is not honest, and the public wants as much protection against the impositions of the print-publishers as the latter once did against the much maligned pirates. The same man who would be ashamed to rob anyone of sixpence, nevertheless is willing to save his conscience with the flattering unctious that the tricks of his trade are legitimate, albeit he has imposed upon a customer, and actually obtained from him, by false pretences, a sum of many pounds, by representing as "proofs" those which are simply impressions! Believing there may be some misunderstanding as to what "proofs" really are, it may be well to mention that they *should* simply be early copies, that are struck off on fine, or India, paper, before publication, to enable the engraver and publisher to test the accuracy of the work. But when the plate is finished, and we have the authority of Mr. Joubert for stating so, it is customary for the engraver to receive as his "right" two-thirds of all proof impressions actually printed before the delivery of the plate to the publisher, though we have no index as to the number of dozens to which the said "right" extends.

We have perused numerous accounts of trials, both civil and criminal, against persons who have infringed the Copyright Acts. In some of these the plaintiffs have sought to assume special damages in consequence of the sale of piracies of their

\* The Stationer.

works, and have produced witnesses to prove that since the piracies were issued, the sale of original copies has fallen off. In the case of *Gambart v. Slater*, tried in the Sheriff's Court, one Mr. Ginger, of Canterbury, swore that he had procured £70 worth of orders for the "Light of the World," when it first appeared, but that afterwards he could not find buyers. Surely this assertion did not prove anything? Every book-publisher knows that the sale of each work is greatest when first issued, and that it gradually declines. And of course it is so with prints. Had Mr. Ginger stated that he had continued to be as successful in finding customers as he was when the print first appeared, we should have disbelieved him. It is, however, only fair to Mr. Gambart to state that so convinced was he of the loss he sustained by having his works pirated, that in 1864 he purchased certain pictures without the copyrights, because he considered the latter useless to him; and in the same year, writing upon the subject, he remarked:—

I withdraw from an industry in which some people think I have rendered some service to art and artists; I do not deem it advisable to waste more capital on property which I am unable to defend, and I am driven out of a lawful business by the evil proceedings of others.

Before concluding our remarks respecting "The Light of the World" and its assumed depreciation, it is not unworthy of notice that Mr. Gambart found it to his interest to re-engrave and publish a smaller copy of the work in question.

Some time ago Mr. Ordish was summoned at the Guildhall for selling a copyright carte-de-visite of Miss Lydia Thompson, but Alderman Carter dismissed the summons on the ground that the defendant had acted in ignorance. The law presumes that every man ought to know when he commits an error; and if the worthy alderman did not decide exactly in accordance with judicial tradition, he took a common-sense view of the case. And we believe that many poor country tradesmen who have had "to pay the piper," through selling piracies in ignorance of their liability, would have done better by appealing to a jury than by showing the white feather, and paying a sum of money to stay the proceedings of their prosecutors. It is only a comparatively few months ago that a great number of newsvenders in the country had actions brought against them at the suit of Moore, MQueen, and Co., and Ernest Gambart, for selling copies of "The Return from Hawking" and "A Distinguished Member of the Humano Society," which had been given away by the publishers to the subscribers of *Bow Bells*. Much annoyance was caused in consequence to very poor people, and in the Thames Police Court it was stated that from a needy widow, living in a by-street, £12 were demanded for compensation, though the total number of copies she sold was only twelve, and from which the profits realized amounted to just fourpence. This was indeed practising the *lex talionis* with a vengeance!

Messrs. Graves and Co. suggest that as some 700 pictures are annually exhibited at the Royal Academy, there must be many of such worthy of being reproduced; and they propose that a public company should be established for the purpose of disseminating "cheap art." The hint is not altogether a bad one, and we have no doubt that many artists would, for a fair consideration, permit their paintings to be photographed, and copies of them to be sold. But then the difficulty arises of getting good negatives from pictures, as the effect produced by pigments is generally blotchy, and lacks that defined sharpness which is obtained from engravings. In France, however, this difficulty is overcome. There the artists and photographers work in harmony. The former first prepare their designs in sepia, and from these the latter work, while the colours are subsequently added by the painter.

In speaking of the law of copyright, Lord Mansfield said:—"It is certainly not agreeable to natural justice that a stranger should reap the beneficial pecuniary produce of another man's work." And in this expression we fully coincide. As the law, however, exists, there is no direct means to discover what prints and what photographs are copyright. Dealers in such goods may therefore very innocently transgress the law, and subject themselves to heavy penalties; particularly so at the present time, when unscrupulous men are employed to tempt unwary people to buy, and still more unscrupulous individuals are willing to tempt the before-mentioned purchasers to sell. There is a great demand now existing for photographic pictures, and we think the print-publishers are doing a moral wrong, firstly, by not endeavouring to satisfy the public requirements; and, secondly, in omitting to issue details of those goods in which they claim a copyright. Trading in

photographs is now very hazardous, and we advise dealers to be chary as to their proceedings, and to purchase only of established firms of good repute, conditionally that the said firms will hold them harmless in any ulterior proceedings that may be taken against them in respect to their dealings in such goods. There are many works represented as copyrights that are not such, while there are numerous plates concerning which there is much doubt. These circumstances cause much difficulty to even the most experienced persons connected with the trade; and as reliable evidence is not always attainable, errors are unwittingly made. The existing position of the scrap trade is, therefore, so unsatisfactory, that we think legislative interference is requisite. If a person publish a book, there are, by reason of the many indices that are issued, means of finding out the nature and title of the work, while the volume may be readily seen and perused at the British Museum. With works of art it is different. An individual may desire to reproduce a particular design in photography. If, however, he exercise all his personal ingenuity in endeavouring to discover whether any copyright exists in it, he will probably fail to secure correct information. At Stationer's Hall he will not learn anything unless he know the name under which the design has been entered, while even if this be known, the description may be so ambiguous that he will fail to recognize it as referring to the work he wishes to reproduce; for be it known, that it is not requisite on registration to supply a copy of the work desired to be protected. We therefore suggest the establishment of a museum of art, which should be open to all persons wishing to make inquiries respecting copyright, and where photographs should be kept of every protected work, whether statue, painting, print, or photograph. Such an establishment would probably be more effectual in putting down piracies than have been the late criminal prosecutions, as it would wholly prevent pleas of ignorance or other illusive excuses being made in extenuation of error.

Certain judicial decisions recently given have caused much consternation among the dealers. Fines of £250 and £130 and expenses, irrespective of civil proceedings at law, are not of every-day occurrence, and may well strike terror into the camps of the pirates. Whether the decisions arrived at by the magistrate were, or were not, right we shall not discuss, though we consider they were cases in which leniency might have been shown. We do so because it was proved in evidence that the prosecutor's spies tempted the defendants to procure particular goods on the faith of certain representations, and an old maxim states that "the tempter is worse than the thief," though we do not believe that the last word of it is any way applicable to the defendants. They were not dealing in the piracies, and the spies, finding out such to be the case, made tempting offers, and, poor human nature not being infallible, the scouts succeeded in hunting down their game. They did not, however, bag them at once, but let months roll away, and when their victims had almost forgotten the circumstances of their delinquency, the avenging summonses were issued. If several persons combine together for the purpose of inducing others to commit legal offences, it appears to ourselves very much like a conspiracy. In all cases, therefore, where prosecutions are instituted on the evidence of hired temptors, or spies, we would award the very lightest punishment that the copyright law allows. R. H. M.

## Proceedings of Societies.

### SOUTH LONDON PHOTOGRAPHIC ASSOCIATION.

THE usual Monthly Meeting was held in the City of London College, on the evening of Thursday, April 9th, the Rev. F. F. STATHAM, M.A., in the chair.

The minutes of a former meeting were read and confirmed.

THE CHAIRMAN announced that the presentation prints selected for the present year were "Going to Markot," 16 by 12, by Mr. H. P. Robinson, printed in carbon, and a whole-plate picture by Mr. Rejlander, entitled "Homeless," printed in silver. He also called attention to a circular inviting photographers to contribute to a fine art exhibition at Darwin, in Lancashire.

THE officers for election at the Annual Meeting in June were nominated.

The CHAIRMAN then announced that the evening having been set aside for the examination of photographs and conversation thereon, he would be glad if the members would place before the meeting the examples of the art they had brought with them.

Mr. COCKING (Hon. Sec.) exhibited three portraits, 10 by 8, possessing the characteristics of great richness, force, and depth seen in most of M. Salomon's portraits. All the pictures displayed much artistic feeling: one, of a gentleman, taken under somewhat difficult circumstances as to light, &c., was exceedingly fine and vigorous, possessing excellent gradation and modelling, and unusually fine rendering of light and shade. Mr. Cockin also exhibited a family picture, consisting of father and mother and fifteen children, mounted in the spaces left in an illuminated design which he had prepared for the purpose.

Mr. WHARTON SIMPSON exhibited examples of the work of M. Adam-Salomon, of Paris, and of Mr. Notman, of Montreal, done in a similar style; also of the work of Herr Milstor, of Berlin, and some examples of American carbon printing, all of which were much admired.

Mr. BOOTY exhibited some interesting landscapes, amongst which were some interesting snow scenes and some good cloud effects, obtained by giving a graduated exposure, the foreground being uncovered much longer than the sky.

Mr. DALLMEYER exhibited a large selection of Mr. England's charming Rhine pictures taken on dry plates; of Faulkner's portraits of children; of Mr. Russell Manners Gordon's exquisite landscapes; of Mr. Rojlander's art studies; and some other pictures, all illustrating the qualities of his various forms of lenses.

Mr. BLANCHARD exhibited some remarkably fine, massive portrait studies, and some architectural pictures taken with Dallmeyer's wide-angle Rectilinear lens. He explained, in reference to a view of Cannon Street Station and Hotel, that it would have been impossible to have secured the picture with any other lens, on account of the contracted situation. The view in question was taken from the opposite side of the street, and although the perspective was somewhat exaggerated by taking such a large picture with a lens of such short focus, he considered such a lens an invaluable addition to the photographer's stock of apparatus, enabling him to secure many valuable pictures before beyond his reach.

Mr. ENGLAND said that many of the pictures he then exhibited were taken with the rectilinear lens, and could not have been taken without it—that of Cologne Cathedral, for instance, which had never been taken before, its contracted situation rendering it impossible with ordinary lenses. This picture, although of cabinet size, was taken with a lens of  $4\frac{1}{2}$  inches focus. In using such a lens he avoided, where he could, such a point of view as would render the exaggerated perspective very apparent.

Mr. DALLMEYER pointed out the importance of employing special lenses for special uses, and of avoiding the wide-angle and short focus lenses for ordinary purposes. Whilst he had endeavoured to meet the wants of photographers by giving them instruments to suit occasional and special necessities, he would recommend that for ordinary purposes a lens including about  $54^\circ$  should be used, which would give results natural and true, without any appearance of false perspective.

Mr. HUNTER exhibited a large and interesting collection of the photographs of the Amateur Photographic Association.

Mr. WALL exhibited a print from a negative in which an etching-needle had been used to modify the detail in the accessories and background, and also some examples of a method of producing, by photography, blocks for surface-printing from copies of engraving.

Mr. WERGE exhibited an interesting series of pictures illustrating eight distinct types of photography. Mentioning them alphabetically rather than chronologically, they were the Ambrotype, or collodion positive on glass; the Calotype, or paper print, by Fox Talbot's method; the Chrysotype—one of Sir John Herschel's processes—in which the sensitive surface was prepared with ammonio-citrate of iron, and developed with gold; the Cyanotype, another of the processes of Sir John Herschel, in which the image was produced by the aid of prussiate of potassium; the Daguerreotype, a portrait of the wife of Daguerre, taken by himself; a Diaphanotype, which was a paper print made transparent, and coloured at the back in oil; a Ferrottype, or Collodion-positive, on an enamelled iron plate; and an Ivorytype, or paper print, coloured on the surface in water-colour, and rendered transparent with wax, so as to re-

semble a tablet of ivory. Mr. Werge also exhibited a print on albuminized paper, printed twelve years ago, which was in very perfect condition, showing no fading or change of colour. It was washed as described at a recent meeting by Mr. Werge.

After explanation and examination of these and other prints, the proceedings terminated.

#### LONDON PHOTOGRAPHIC SOCIETY.

THE usual Monthly Meeting of this Society was held in the Architectural Gallery, Conduit Street, on the evening of April 14th, Mr. J. GLAISHER, F.R.S., in the chair.

The minutes of a previous meeting were read and confirmed.

The CHAIRMAN said that Mr. Mayall had kindly promised to add to the list of presentation prints already announced by giving each member a photograph, the subject of which remained to be decided by the council or the donor.

Mr. GRIGGS then proceeded to read a paper on Photolithography, and the application of Photography to Chromo-lithography, describing in detail the process employed at the India Museum in producing the designs of textile manufactures and other art industries for distribution amongst the manufacturers of this country. A salient difference in his operations to those usually employed in the recognized processes of photo-lithography consists in the fact that he washes his transfer with cold water instead of boiling water. An especial interest was communicated to the proceedings by the practical demonstration of the operations which was afforded, Mr. Griggs, with the aid of an assistant, printing, in presence of the meeting, certain impressions from two stones forming the design of a turban piece. He also washed off a transfer before the meeting, placed it on the stone, rolled it up, and distributed a few impressions among the members.

The CHAIRMAN called attention to some excellent examples of photo-chromo-lithography Mr. Griggs had placed at the disposal of the Society for presentation to members as examples of the kind of work he had described, and the mode of producing which he had demonstrated. Members would receive the prints at the close of the meeting, on application to the Secretary. He also called attention to a fine collection of views on the Rhine, produced by Mr. England on dry plates; and to a number of fine examples of the Eburneum process, produced by Mr. John Keene.

Mr. MAYALL expressed his personal thanks to Mr. Griggs for the reading of one of the most interesting papers, accompanied by the most satisfactory illustrations, that they ever had the pleasure of witnessing. He was deeply impressed by what had been brought before them, of the immense strides which photography was making as a handmaid to manufacturing art; he had scarcely been prepared to expect that photography should be made the agent of distributing the splendid designs of the textile fabrics of India to every manufacturer in this country, rendering them with a degree of accuracy which gave the value of technical pattern for actual guidance in work. The manufacturers of Manchester and Paisley must at once see the importance of guides so accurate and perfect, and the result must be beneficial in our art industries. This was an illustration of how photography might be made valuable in cultivating our workmen in connection with all industries involving the art of design; and he hoped to see the admirable productions of the middle ages, the works of Cellini and others, made familiar by a similar means. He hoped, too, that the manufacturers of this country, availing themselves of such aids to design, would send back to India fabrics which should illustrate their triumphs in manufacturing industry. Doubtless Mr. Griggs' process would have many valuable applications, especially in chromo-lithography. He should like to learn from him if these designs could be produced in cylinders, so as to fit for the purpose of the calico-printer, where it might probably be of incalculable value. He foresaw immense advantages in this respect, in the designs of the fabrics produced in our cotton districts, when true art being wedded to manufacturing industry, the two going hand in hand, aided by such appliances as Mr. Griggs had brought before them. All true art required the devotion of a life study to give it value, and in proportion as true art could be multiplied and popularized it would drive out the bad art which was only too common. The process illustrated to-night would give currency to the productions of such men as Albert Durer and others of a high class. It was too true that we were, in this country, behind the rest of Europe in the arts of design. He

had had the pleasure of examining the great book opened in Paris last year—he meant the International Exhibition—in company of four of the master minds of this country, of which Sir Charles Wheatstone was one, and they were painfully struck with the inferiority of this country in the arts of design: with manufactures which might enable us to clothe the world, we had yet much to learn in this respect. He hailed, therefore, with great delight every agency which should advance us in this respect, and enable England to maintain its position in the progress of art and industry, and preserve its superiority in our time, as it had in bygone ages.

In answer to a member as to what were the essential features in this process differing from that of Sir Henry James, Mr. GRIGGS said that the essential point was the fact that he washed away the superfluous matter from the transfer with cold water, and Sir Henry James with hot water. By doing this Sir Henry James removed all the gelatine as well as the ink from the lights; whereas he (Mr. Griggs) only removed the ink, leaving the gelatine, which gave him an advantage in transferring, the gelatine causing the print to adhere to the stone, without risk of moving, when passing two or three times through the press in transferring. His paper also received a preliminary coating of starch. In answer to Mr. Mayall, he thought that there would be no difficulty in transferring impressions on to a cylindrical rollers.

Mr. PETER LE NEVE FOSTER, in answer to some remarks, said that the essential distinction between the transfer of Mr. Griggs and Col. Sir Henry James was, that the latter removed everything, both ink and gelatine, from the transfer, and Mr. Griggs removed the ink only, leaving the gelatine in the lights.

Mr. MAYALL thought Sir Henry James' process was excellent for maps, but it struck him as scarcely equal to Mr. Griggs' for artistic purposes, the latter having more delicacy.

Mr. GRIGGS did not wish to make claims to superiority, but his aim in leaving the gelatine was to support the fine lines, as when they were left in relief and all gelatine removed, they were apt to break down under the pressure of transferring.

The CHAIRMAN, in a vote of very hearty thanks to Mr. Griggs for his interesting and practical paper, said that every one was indebted to Sir Henry James for having so early published his process in a blue book, and so prevented it being locked by a patent, which it would otherwise have been. The process of printing in various colours was, in his own estimation, of peculiar interest, on account of the nicety and mathematical accuracy necessary in securing the register of the prints produced from such a number of stones. He felt sure they would heartily thank Mr. Griggs for his paper and for the valuable practical demonstrations.

The thanks were expressed by acclamation, and were duly acknowledged by Mr. Griggs.

The CHAIRMAN then read the following letter on the subject of Mr. McLachlan's discovery:—

“Dr. Hugh Diamond, Honorary Secretary of the Photographic Society.

“SIR,—We have the honour to report that on the 12th February last we met Mr. McLachlan by appointment at the rooms of the Society of Arts, and that he then explained to us the principles of a scheme of photographic practice by which he claims to have excluded many difficulties and sources of failure in the production of collodion negatives. Mr. McLachlan attaches great importance to the selection of particular qualities of certain photographic chemicals, samples of which have not, however, been submitted to us.

“Without such aid to guide us, experiments were conducted at Woolwich with the ordinary materials, and we succeeded in realizing some of the conditions promised by Mr. McLachlan.

“The question as to how far the permanence of the bath and uniform working of the collodion and other chemicals may be guaranteed according to this plan must be left for future experiment to decide.—We are, sir, yours &c.,

“P. LE NEVE FOSTER, M.A.

“JOHN SPILLER, F.C.S.”

The CHAIRMAN then said that Mr. McLachlan had come from Manchester that day purposely to communicate to the members of the Society his valuable discovery, but it was unfortunately too late to go fully into it. He would ask him to give them briefly some information as a preparation for the paper he promised to read next month giving fuller information.

Mr. McLACHLAN said that as what he had to communicate

was the result of almost a lifetime of experience to which almost everything else had been sacrificed, he could only very partially enter into the subject in the short time then possible. He had been led to examine the subject from his experience, which resembled that of all photographers, namely, that things would work well for a week, and then, for a week or two more, almost everything would go wrong. As they were using the same things it was clearly a question of condition of the chemicals, which, if kept in a proper state, ought to guarantee immunity from all failures except those of manipulation. After briefly stating the common practice in photography, and its uncertainties and troubles, he said his aim had been, then, to prepare his bath and his collodion so that pure iodide of silver would be formed in the film in equivalent proportions, without the disturbing influence of acid, which tended to separate the iodide from its base. He had succeeded in preparing a bath without acid, which could not be charged in excess with the fatal source of pinholes—iodide of silver—which, while holding oxide of silver in solution, would not fog the plate. Then he prepared collodion to suit the bath, and for convenience he modified commercial samples. As usually sold, all collodions were made from cotton prepared with an excess of sulphuric acid: they contained an acid, not sulphuric acid, but something analogous to it; this caused streaks, brain-markings, &c. It was held by photographers generally that nitrate of silver was not altered by light. Now he found it was altered, and this was an important element in his conclusions. His method was as follows:—He took crystallized nitrate of silver, not the recrystallized. By preference he used a black-looking sample, which was generally rejected; it seemed moist and dirty, and appeared to contain a good deal of the water of crystallization. Members could best judge of what he meant by examining the sample he now exhibited. With this he made a bath, at the rate of one ounce to one ounce of pure distilled water. Taking six ounces of solution so prepared, and putting it out in a 40-ounce bottle to the action of light, he left it as long as he could. He preferred three months of the warmest and sunniest portion of the year; but one month, or even less, would do a good deal. If the water and silver were pure and neutral, no apparent change would take place; if the solution were made either acid or alkaline, the effect of light was considerably limited. Now, to test the change effected, he made a solution of caustic potash, 1 grain to an ounce of distilled water. If a drop of this were added to an ounce of the silver solution before it were sunned, a turbidity would be caused by the precipitation of oxide of silver; but after the sunning, on adding the potash solution, the bath would have been found to have acquired the property of holding oxide of silver in solution; and although a considerable quantity might be formed, it was redissolved, and the solution remained clear after shaking up a little. Practically, he only added 1 drop of potash solution to 1 ounce of silver solution, so as just to secure a slightly alkaline condition. He then took 2 grains of iodide of potassium and dissolved in a very small quantity of water, say 10 minims; this he added to 10 or 12 minims of the strong silver solution, which was then diluted to the strength of 35 grains to the ounce, and, singularly enough, no precipitate of iodide of silver was formed on dilution, nor would any indication of the presence of excess of iodide of silver be present on working. After the lapse of a few days, however, a curious change took place: the iodide of silver was all precipitated suddenly, and after that, no matter how much water was added to dilute the bath, no turbidity or apparent presence of iodide of silver was produced. This was the bath in perfect working order, slightly alkaline. He next prepared a suitable collodion; and, for simplicity, he would mention one excellent sample of commercial collodion—he referred to Mawson's. He would take this in a ripe, red, acid condition. If used in the bath as prepared, it would give brain-markings and stains, because of the antagonism of conditions. It must be made to harmonize with the bath. He therefore took the potash solution and added about 4 drops to a 5-ounce bottle of collodion; this neutralized the acid, making the collodion nearly colourless; and this neutral collodion employed in this alkaline bath would give clear brilliant negatives without a trace of fog, at once delicate and vigorous. He required, however, for the best result, a suitable developer. For this he preferred the common dark green dirty-looking protosulphate of iron. But as it was often more difficult to get this than the clean, pure, light green crystals, he would describe his mode of making the developer with the pure sulphate. He took 16 ounces of a 12-grain

solution, and added to it 5 drachms of methylated alcohol; he placed the bottle containing this on a piece of wood in a saucepan of cold water, and allowed it to come gently to a boil, continuing the boiling for about ten minutes. To this he added 3½ ounces of glacial acetic acid, and then filtered; this flowed over the plate evenly at once, and gave admirable results. With the common sample of iron he made a similar solution, but he added to 1 ounce of alcohol 2 drops of the potash solution, and of this alcohol added 5 drachms. In this case the solution should be warmed, but need not be boiled. The same acetic acid would of course be added. Mr. McLachlan gave many explanations and cautions, but we have here endeavoured to present the salient parts of his operations until he have opportunity of doing himself full justice in a written paper.

A vote of thanks was passed to Mr. McLachlan, and Mr. MAYALL proposed that a committee, consisting of Mr. Bedford, Mr. Sebastian Davis, and Mr. H. P. Robinson, be formed to work experimentally with Mr. McLachlan, and report.

The CHAIRMAN said the Society could scarcely appoint a committee which should in any way control Mr. McLachlan in selecting his own mode of putting the matter before them, but that he would doubtless be glad to receive the assistance of those gentlemen.

Mr. MAYALL explained that his aim was to give weight to Mr. McLachlan's statements by experimental confirmation; and it was arranged that the gentlemen named and Mr. Mayall should further communicate with Mr. McLachlan.

After a few further remarks the proceedings terminated.

## Correspondence.

### PHOTOGRAPHY AND DISEASE.

SIR,—I have often been pleased with the interest taken by you in the personal welfare of the followers of the art of photography, no matter whether professional or amateur, proficient and highly successful down to the veriest tyro; all alike have your sympathy; candidly and truly do you advise with your readers.

Well, now, you recently opened your columns to discuss the subject of the health of photographers; and that subject, one of the most vital to every human being, has for many years been ever present to my own mind, sensible as I have always been that I was practising a business that was, in its very nature, prejudicial to my health unless I exercised great continued care. I have always exercised care, and, with the blessing of God, I have had my reward. I am an old photographer, and I may say that I am not a young man—over 50. I do not boast, but state simply as a fact that I enjoy robust health. For this blessing I am thankful. From the days of Daguerreotype I have led an industrious and energetic life, and hundreds of times, at the end of a hard day in the glass house and dark room amongst heat and chemicals and excitement, I have been thoroughly exhausted; but I have lived out of town (I am a photographer in a large provincial town), and intend to continue to do so. After business is over, my plan is to take the 'bus, if tired or bad weather, and get away into the country to my residence, which is well ventilated, and where we have an abundance of fresh air; of that fresh air I have a good drink before I return to business next morning. I am thoroughly refreshed mentally and physically, and am ready buoyantly to face either customers, chemicals, or anything else in reason. I may say that, although not a teetotaler, I am a very temperate man, and make it a rule not to drink intoxicating drinks during business hours. I take a very light lunch at mid-day, and after business is over I make a substantial meal. In conclusion, I may say that I cannot see how a photographer can expect to have good health, or, any how, robust health, when, especially in large towns, he "lives on the premises," carrying with him to bed the fumes of the cyanide and other poisonous drugs, permeating and clogging the whole system, and rising next morning unrefreshed, restless, enervated, and almost lifeless. Is not this the case with many of our brothers in photography?—I am, sir, yours respectfully,  
YORKSHIRE.

### SOME DRY PLATE HINTS.

SIR,—If the following hints are of any use to the photographic world perhaps you will allow them space in your valuable columns.

I have for some time been using England's dry process with the greatest success, and am only too glad to bear testimony to its value. I have used the formula laid down in your YEAR-BOOK approximately. In the albumen, I have varied the proportions of water, using half-and-half, and sensitizing with from 30 to 10 grains of silver, according to the temperature of my operating-room. As I have never found any difference caused by the heat during exposure, even though the plate be kept a month in hot weather after being sensitized with the 30-grain solution, I have used collodion bromized with from 2 to 4 grains of bromide, and with the latter have found that the plates absolutely improve with keeping up to a month; and that in no case deterioration takes place in them for three weeks. I have also found that the exposure given to the plate signifies little, so long as it has between three times and six times the exposure necessary for wet plates. Below or above these points the negative is under or over-exposed. In the south of France, where I am at present residing, the houses suffer from the "no tap" system, the French seemingly having an objection to more than the smallest quantity of water inside their habitations. I advise speculators in water works schemes to have nothing to do with those that may be proposed for the towns out here). This is a serious drawback to the pleasant preparation of these plates. I have adopted the system in consequence of washings in trays partly. I coat, sensitize, and lay the plate in a dish of water, face upwards; coat, and prepare another; take the first plate out of the water, swill, albuminize, and sensitize as usual; swill, lay in a dish with sloping sides, face downwards, till the next plate is ready to take its place; swill again, and set up to dry. Pictures are always much more satisfactory if development ensues before thirty-six hours after exposure. I have found that the negatives, after a longer interval, are weak, as a rule. The coffee process is very sure, but the exposure is too long to please me, being eight to ten times that of wet. The negatives obtained by it are very good, but the right amount of washing is important to be attended to; extra washing diminishes the sensitiveness amazingly.

In conclusion, let me recommend a receipt for using up the yolks of the eggs used for the albumen:—To two yolks add one glass of sherry and one of milk; beat up well with powdered white sugar, a little nutmeg, and a teaspoonful of brandy. The mixture taken internally before commencing adds materially to the good preparation of the dry plates, and a similar dose afterwards is not amiss.—I am, &c.,  
R. E.

April 10th, 1868.

## Talk in the Studio.

PHOTOGRAPHY AND THE ABYSSINIAN EXPEDITION.—The official report of Lieut.-General Napier in regard to the operations of the Abyssinian Expedition states that the photographers of the Expedition have been employed in photographing plans and views, as well as surveys of the route onwards, prints of which are handed over to the commanding officers of corps previous to the march.

PHOTOGRAPHIC IDENTIFICATION.—A singular instance of doubtful identity has recently occurred, in which even a photograph was insufficient to give certainty. The body of a man was discovered in a newly-built house at Hackney, and in regard to which the curious difficulty of identification has arisen. Two medical men identify it as the body of an escaped lunatic named Heasman, and his brother confirms their statement. A lady identifies it as another person, her missing husband, and her two sisters confirm her identification. Another lady produced a photograph of a missing relative, which bore a far more striking resemblance to the deceased than did either of two photographs subsequently shown by Mr. Heasman as those of his brother. The incidental circumstances seemed, however, to give the most weight to the supposition that the body was undoubtedly that of Heasman the escaped lunatic.

**ANTIDOTE FOR CYANIDE.**—The injurious effect on the skin produced by cyanide of potassium in electro-plating establishments is completely arrested and ulcerous sores prevented by anointing the hands with a mixture made by incorporating protosulphate of iron in fine powder with linseed oil.

## To Correspondents.

**PUNJABEE.**—It is not difficult to cover a stout wire with gutta-percha to form a dipper, but it requires constant observation to see that no portion of the gutta-percha gets removed, so as to bring the metal into contact with the silver solution. Take a strip of thin sheet gutta-percha, wide enough to meet round the wire, soften by immersion in boiling water, dry carefully, then envelop the wire, making the edges wrap over a little. The flame of a spirit-lamp or a piece of hot metal will then melt the edge of the sheet sufficiently to make it adhere like a soldered joint: or, another, and perhaps better, plan consists in taking the thin sheet gutta-percha like thin paper, and cut into narrow strips; heat the wire, and wrap round the gutta-percha spirally. When once covered, pass it through the flame of a spirit-lamp, and with moistened fingers press it down to cause all the edges to join. Repeat this process until a sufficient covering is secured. As a rule, we prefer glass dippers, as they are most easily made, most easily repaired, and under no circumstances injure the bath. If a little gutta-percha or india-rubber be attached to the bottom, the risk of knocking out the bottom of a glass bath is avoided.

**SCIENTIA CUM ARTE.**—The yellow spots in the print enclosed are undoubtedly due to imperfect fixation. Vignettes are much more subject to risk of imperfect fixation than fully printed out prints, as you will readily perceive on a little reflection. The more perfectly a print is covered with dark objects the more perfectly all the chloride of silver in the paper is reduced, and the less there is for the fixing bath to remove. The more white there is in a print—as in a vignette, for instance—the more unaltered chloride of silver it contains when it is immersed in the fixing bath. Therefore, if the bath be rather weak, or a little exhausted, the vignettes, or prints containing most unaltered chloride of silver, will suffer first and most. Three ounces of hypo to the pint of water will give a somewhat weak bath, which will readily get somewhat inert after fixing a batch of prints. We prefer at least 4 ounces to the pint, and 5 ounces are better, especially where vignettes are concerned.

**J. R. L. M.**—The trustees, as we explained some time ago, have been acting under legal guidance from the first. The communication to which you refer was a tissue of mis-statements. Subscribers could at any time obtain information from the trustees, as many have done satisfactorily. Non-subscribers have no concern in the matter.

**J. G. B.**—A vessel for the nitrate bath made of pure silver might, of course, be used, but we cannot recommend it. The baser metal used in soldering would undoubtedly be attacked. Any excess of nitric acid would also act upon the metallic silver. A glass bath in a wooden case is quite safe, with fair usage, for travelling; or, wood lined with pure thin sheet india-rubber may be used.

**SOUTH DEVON.**—The solution of iodine 1 grain, iodide of potassium 2 grains, in water 1 ounce, is a stock solution, of which, for the clearing process to which you refer, something less than a drachm should be added to an ounce of water. A very dilute solution of iodine will serve to convert the abnormal deposit on shadows into iodide of silver; and this is all that is required. If any portion of the actual image is converted into iodide, it will, of course, be dissolved by hypo or cyanide, and so impoverish the image.

**P.**—There are several toning baths which keep well and reduce very little; but only one, that we remember, that does not reduce at all. The sulphocyanide bath keeps well and does not reduce at all. Dissolve 1 grain of chloride of gold and from 46 to 60 grains of sulphocyanide of ammonium in 3 ounces of water. This may be used at once, or will keep any length of time. The acetate bath, containing 1 grain of chloride of gold and 30 grains of acetate of soda in from 4 to 8 ounces of water, may be used in a couple of days, or will keep for months; it yields a warm tone, and reduces very little. The lime bath, containing from 1 to 2 grains of chloride of lime and 1 grain of chloride of gold in 4 to 8 ounces of water, is best not used for a week after it is mixed, and will keep for months; it yields a black tone, and reduces less and less as it gets older. 2. To keep a plate moist after development, so as to intensify and fix at leisure, coat the film either with a mixture of equal parts of glycerine and water, or equal parts of golden syrup and water. We prefer the latter. This will keep the film moist many hours; after washing it off, the image can be further intensified, if necessary, or fixed at once. 3. If you will describe the details of your morphine operations, we can probably account for the failure. 4. When

development is tardy with Mr. England's plates, he adds a trace of ammonia to the plain pyro, which rapidly brings out an image.

**BETA.**—You will find a full description of the "vitrified sheet india-rubber" and its probable applications upwards of a couple of months ago (February 7th). Actual experiment will be necessary to test its practical value. When it is ready for introduction into commerce we shall have more to say about it. We have examined a sample: it is something like goldbeaters'-skin, but a little thicker. It will be sold in sheets; the price we cannot state.

**W. J. A. G.**—If morphine be used for preserving moist plates, all free nitrate of silver must be first thoroughly washed away. For keeping a plate twenty-four hours, perhaps the glycerine process is best; you will find it fully described on p. 231 of our Volume for 1867. If you describe in detail the operations you employ in the process which gives you so many failures, we can probably point out their origin.

**WATERLOO.**—You may, without serious results, use the same solutions for plain paper which you employ for albuminized paper, although the solutions for one are not always the best for the other. The dirty yellow of the paper you forward is due to imperfect fixation, and arises, probably, from the use of an exhausted fixing bath; it may possibly arise from keeping the paper sensitive some time before use, or, rather, before fixation; in which case a decomposition has ensued in the combination formed between the silver and the sizing matter of the paper, leaving a dirty, insoluble compound on the body of the paper. This you may see on examining it by transmitted light. Plain salted paper has a right side and a wrong; the right side has the smoothest, finest surface.

**J. TAYLOR.**—The letter has been addressed and forwarded.

**W. CROUCH.**—Your negatives having the appearance of positives instead of negatives is due to insufficient exposure and insufficient development. The negative of the print enclosed has either been much out of focus, or you have printed with the wrong side in contact with the paper. 2. You cannot tone after fixing, satisfactorily; but you may, without danger, use sufficient light in toning to examine the progress fairly. A lamp or a candle would do no harm to the toning print, nor would an occasional glance by dull daylight. 3. If the film of the negative stick to the paper, there is little hope of preserving it. It is the result of imperfect varnish, or of using the negative too soon after varnishing. Let us hear further of your progress. You have no need to be discouraged with the results of your first week's practice.

**J. MILLER.**—The 1B long of the same maker will answer your purpose best. The front lens may be used as a landscape lens. 2 No, to both parts of the question.

**J. C. G.**—No. 1 is most suitable, and No. 4 least suitable.

**L. B.**—The print is from an imperfect negative, thin and foggy, apparently; it is too lightly printed, and is over-toned; hence the grey, flat appearance which puzzles you. No amount of toning will give you deep blacks without a sufficient deposit of silver to begin with.

**R. D. (Devizes).**—Your doublet in preference to your single landscape lens for copying plans. 2. Willis's process is a patented process.

**H. P. W.**—We are not familiar with the especial lens you describe; but it doubtless requires the same treatment as similar portrait lenses. To use it for landscapes the back lens must be removed altogether, and the front lens reversed, so as to present its concave side to the landscape. The stops being placed in their ordinary places will now be in front of the front lens (which is screwed in the back cell) as nearly as circumstances permit, in the proper place.

**B. C.**—The effect you describe is fog. It may proceed from a variety of causes; but most likely from the condition of the bath. Try, first, the addition to the bath of a drop or two of nitric acid. If that does not effect a cure, take a 10-grain solution of bicarbonate of soda, and add a few drops at a time until the bath remains turbid; then expose for a few days to the sun; filter, and, after adding a drop or two of acid, try again. The use of a newly-mixed collodion, or of newly-mixed developer, will conduce to fog.

**G. R. FITT.**—We will examine the precipitate, and report. Thanks for the communication on the Honey Process, which will appear in our next.

"LUX GRAPHICUS on the Wing," and several other articles, are compelled to stand over until next week.

Several Correspondents in our next.

All Communications for the Editor to be addressed to 15, Gough Square, Fleet Street, London, E.C.

\* \* \* All photographs forwarded to the Publisher for registration receive attention at once; but the pressure on our space sometimes compels us to defer the acknowledgment in this column. It should be borne in mind, therefore, that non-acknowledgment at once does not necessarily imply non-receipt or non-registration.

### MR. McLACHLAN'S DISCOVERY.

ONE essential feature in the mode of working recently propounded by Mr. McLachlan involves specific advantages and disadvantages. The fact that a protracted sunning is necessary to prepare the nitrate bath involves the disadvantage that photographers cannot arrive at a practical decision at once as to the value of the method proposed; but it also involves the advantage of checking hasty conclusions, and rendering necessary patient experiment and time for careful thought before an absolute decision is made. In the meantime it is probable that various questions will be asked, and further explanations will be sought from Mr. McLachlan; and, as is the custom with almost every new method or modification introduced to photographers, the novelty and value of Mr. McLachlan's proposals will be freely challenged and discussed. If this be done in a proper spirit, and for the purpose of eliciting truth, we shall have pleasure in aiding a thorough ventilation of the question. As time and opportunity will be required for testing by experiment the methods described, we shall for the present forbear comment on the subject; but as Mr. McLachlan has kindly undertaken to give such explanations in our pages as may from time to time seem necessary for the elucidation of his improved mode of working, we shall have pleasure in receiving the questions of those interested in the matter.

We shall append here extracts from some letters we have received, asking some questions on the subject; and we may here reply to several querists as to what is the character of Mr. McLachlan's photographs, and how far they bear out his claims to an improved mode of working. We have recently seen a large number of the prints obtained from negatives produced in such a bath as Mr. McLachlan describes, and they undoubtedly possess the highest technical excellence, being exceedingly clean, delicate, and brilliant, and free from defects. One correspondent, signing "Theta," writes as follows:—

"Will you be so good as explain whether Mr. McLachlan insists on absolutely alkaline conditions, or whether he adopts the method described simply to ensure neutrality?"

"If the absolutely alkaline condition is necessary, how does the capacity of the bath to hold oxide of silver in suspension prevent fog, which is often the result of oxide of silver which has been held in solution becoming precipitated all over the plate instead of on those parts only where light has acted?"

"If the neutral condition only is required, is it not a revival of the condition so often insisted upon by the early collodion photographers at a time when iodized collodion only was employed? I believe that many old photographers now hold that a neutral bath made from pure nitrate of silver, and an iodized collodion in good condition, without any bromide, gives the most perfect negatives.

"Is it not a fact that amongst the advantages conferred by the use of bromides in collodion, one of the chief is, that they have rendered unnecessary a degree of purity in all the chemicals difficult to secure and almost impossible to maintain, and that they have permitted the free use of nitric acid as a source of cleanliness without any sacrifice of sensitiveness?"

Another correspondent, "A. Z.," writing on the same part of the subject, says:

"If I understand the statement correctly, Mr. McLachlan works with collodion and nitrate bath as nearly as possible neutral, or just tending towards alkalinity; but I notice there is a compensating element, the influence of which Mr. McLachlan either overlooks or ignores. The developing solution contains an enormous proportion of restraining acid. To 16 ounces of a 12-grain solution  $3\frac{1}{2}$  ounces of glacial acetic acid are said to be added; this gives at the rate of more than eight times as much glacial acid as sulphate of iron, nearly half an ounce of the acid to 12 grains of the iron! And this after some pains has been taken to oxidize a portion of the iron, and produce persulphate, which is well-known to act as a restrainer, and promote cleanliness and freedom from fog and abnormal reduction. It strikes me that, without any especial preparation, clean pictures might be obtained with such a developer even when collodion and bath are neutral or slightly alkaline."

R. G. L. says:—"I am anxious to try Mr. McLachlan's process, and as time appears to be an important element, I do not wish to waste time by proceeding incorrectly. Can you tell me where the peculiar quality of nitrate of silver described as most suitable can be obtained? And can you give a sufficiently precise description of it to enable me to distinguish it when I see it?"

"Failing to procure the quality considered best, what is next best? Or, will any ordinary sample of nitrate answer in its degree? Or, can it be treated in any manner which will make it suitable? If not, and the proper kind can only be procured now and then, how shall we secure certainty in working?"

"I notice that Mr. McLachlan is reported as stating that the effect of light on the solution will be considerably limited if it be either acid or alkaline. As many commercial samples of nitrate of silver contain free nitric acid, I presume that a solution made from such nitrate would require neutralizing before sunning. Is this so? It has been customary to require that a silver solution should be made faintly alkaline before sunning, and I have always found this important, as the action of light on an alkaline solution has been more prompt and complete than on one in any degree acid. Is Mr. McLachlan correct in stating that in his operations the action of light is limited if the solution be alkaline?"

"Assuming that I have obtained a good bath on Mr.

McLachlan's principle, how can I tell when the collodion is in proper condition? Shall I have to add any potash solution to a commercial collodion which is already colourless?

"Finally, suppose all done as Mr. McLachlan has described, and satisfactory results obtained, upon what does the stability of the bath depend, or is it due to controllable causes? On this point I cannot find, from the report, that anything very definite has been said at the London meeting, notwithstanding that constancy in the bath and unerring certainty in the results are, as I understand the matter, chief among the claims made for the new system."

We have selected the letters of certain correspondents for extract here, because they contain questions of a representative character, and make known the difficulties of others. We have divested the extracts of other matter, and placed the questions in a categorical form, to enable Mr. McLachlan to deal with them with as little trouble as possible. Categorical answers to these questions will aid materially in making the matter clear. Some of the questions we might have answered ourselves, but we prefer, at present, to leave the matter for fuller explanation in Mr. McLachlan's hands.

In the meantime we may call attention to an interesting article by Mr. Spiller on the subject, in which the reader has the results of two months of experiment by an accomplished chemist. Mr. McLachlan's experiments and conclusions therefrom have been confessedly of an empirical character. As a practical man, he has worked out specific results of which he feels he can speak positively, but of which he does not undertake to explain the rationale. Mr. Spiller gives what he believes to be the rationale of the matter, and attributes the results obtained to the presence of chloride of silver in the nitrate bath. The peculiar quality of the nitrate of silver upon which Mr. McLachlan lays stress Mr. Spiller believes to be due to the presence of chloride of silver; and he is confirmed in this view by the fact that of two baths with which he has experimented during the last two months, made with ordinary nitrate of silver, one was not sensibly affected by light, whilst the other, to which chloride of sodium had been purposely added, gave the reactions which Mr. McLachlan describes.

We have been asked if Mr. McLachlan has divulged the whole of his secret, or whether he retains something for the promised paper next month. So far as we understand the matter, the promised paper will state many details important to be remembered, but that he has stated without reserve the principles upon which he has found success to depend. On this point we shall, however, allow Mr. McLachlan to speak for himself.

#### MR. GRIGGS' LITHOGRAPHIC PROCESS.

THE process of photo-lithography described and demonstrated by Mr. Griggs at the recent meeting of the Photographic Society has some especial points of difference from all other published methods which are worth noting. We believe that the development of photo-lithography as a branch of industry has hitherto received too little attention in this country, which is behind almost every other part of the world in this especial branch of our art. Although the especial operations of photo-lithography do not come within the scope of practice necessary to the ordinary photographer, yet, in proportion to the growing importance of this branch of the art, it becomes a matter of interest to all photographers to render themselves familiar with the different modes of working, and the respective advantages they present.

The original methods of obtaining a photographic image direct on the stone have, except in a few exceptional cases, been long abandoned for the transfer process first worked out by Mr. Osborne. The modification in Mr. Griggs' process consists in the mode of transfer. The absolute advantage of this modification must be determined by the practical lithographer; but, judging from a *prima facie* examination, it appears to be an unquestionable advantage. In

the ordinary transfer process employed by Mr. Osborne, Col. Sir H. James, and others, the sensitive surface of chromated gelatine, after exposure to light, is covered with transfer ink, and then floated face upwards on a dish of boiling water. The portions of gelatine which, having been protected from light, still remain soluble, are thus softened or dissolved, and are then easily removed by means of a sponge and warm water, with or without the admixture of a little gum and acid. When this operation is completed, the insoluble portions of the gelatine, forming the image coated with the ink, which has adhered to the surface, remain on the paper, all the rest having been washed away, leaving the clean paper only. With a transfer so prepared two difficulties have been experienced. If the coating of gelatine were in any degree too thick, each fine line of the image, standing in high relief, was subject to damage by the pressure used in transferring, and a somewhat blurred effect, from lateral spreading, was sometimes the result. The second risk arises from the danger of the paper containing the image moving in course of the two or three times it passes through the press to secure a perfect transfer of the greasy image to the stone. Mr. Osborne mixes a certain proportion of albumen with his gelatine, which, becoming coagulated by the action of the boiling water, prevents the paper being left quite bare in the whites, and so secures sufficient bite or adhesion to the stone to prevent the paper moving. The plan employed by Mr. Griggs seems to afford a safeguard against both these risks. In his process soluble gelatine is not removed from the transfer. The exposed sensitive paper is soaked for a short time in cold water before the transfer ink is applied; and, after the application, the superfluous ink is removed with a sponge, dipped in dilute nitric acid and gum-water. This removes the ink from the parts where light has not acted, and which are, therefore, still soluble, but leaves the gelatine. The advantages gained are immunity, to a great extent, from the risks we have mentioned. The gelatine causes the transfer paper to adhere to the stone, and so prevents the risk of moving; and it further assists in supporting fine lines, and lessens the risk of spreading and blurring. There are some other modifications in detail, such as the preparation of the transfer paper with starch, for which we refer the readers to Mr. Griggs' paper, our chief object here being to note the difference in principle in the mode of transferring.

We may here mention that we have received a few days ago a very excellent photo-lithographic reproduction of an engraving from Mr. David Duncan, who informs us that he has for some time used the cold method of washing off, leaving the gelatine undisturbed on the paper as described by Mr. Griggs.

It should be noted that the processes to which we are referring are chiefly applicable to the reproduction of images in line or stipple, no recent advance having been made in the rendering of half-tone by means of photo-lithography. Some exceedingly good portraits which have recently been issued as photo-lithographs we are informed, on good authority, do not legitimately come under that designation. They are interesting as excellent illustrations of an application of photography to aid the lithographer, but are not examples of photo-lithography as popularly understood. An enlarged image from a negative is, we understand, printed by a silver process on a finely grained stone, and this image is then carefully worked upon with lithographic chalk by a skilful draughtsman, who accurately reproduces every detail in the photograph. The result is excellent, and the application of our art most legitimate; but it is necessary to distinguish between such a method and the modes of working in which the photographic image is made to give a printing surface without the aid of the draughtsman.

Of the value of the process of photo-lithography, its application at the India Museum is an admirable example, and nothing need exceed the excellence of the photo-

chromo-lithographs produced by Mr. Griggs in illustration of the purpose to which it is applied. Our readers are aware that Dr. Forbes Watson has undertaken the important task of familiarizing the manufacturers of this country with the designs and character of the textile fabrics of India. Photo-lithography lends itself most admirably to this undertaking. Apart from the superior cheapness of photographic delineation to hand-drawing—the cost, Mr. Griggs informs us, is less than half—the accuracy of the facsimile is far superior to anything which could be produced by hand. Every thread of the fabric is rendered by photography; and by the skilful multiplication of the stones all the glowing colours of the Eastern designs are duly rendered. A sight of the examples is more interesting than any description, and we commend all our readers who are members of the Society to fail not in securing the two fine prints placed at the disposal of members, consisting of a gorgeous turban picce, and an exquisite lace shawl patteru, both fine examples of the excellence which generally characterises Indian design.

## OBSERVATIONS ON MR. McLACHLAN'S PROCESS

BY JOHN SPILLER, F.C.S.

THE main features of Mr. McLachlan's recent proposal may be said to consist in the neutralization of free acids and uncombined iodine in the collodion by the addition thereto of a minute quantity of aqueous or alcoholic potash, and in the adoption of a new mode of preparing the silver bath.

For making this last-named solution a special quality of nitrate of silver is preferred, which, according to Mr. McLachlan's description, is occasionally to be met with in commerce in the form of moist and somewhat discoloured crystals. Not having had any sample submitted to me I can only conjecture that the special quality here referred to may contain, besides the mother liquor, either a small proportion of metallic silver, reduced by organic matter, or, more probably, of intermixed chloride of silver, blackened by exposure to light. On the latter supposition, which assumes only the existence of a very commonly occurring impurity in the nitric acid used for preparing the silver crystals, I find no difficulty in accounting for the superiority of results obtained by the use of such a salt in the manner described. The instructions given were simply to dissolve the nitrate crystals in an equal weight, or less, of pure water, and submit the concentrated solution to the prolonged action of sunlight, whereby a small quantity of reduced silver is deposited, and "an acid which does not behave like nitric acid" is said to be liberated. After a sufficient exposure neutrality is restored by the careful addition of an excessively dilute solution of pure caustic potash (or soda), added until the oxide of silver thus precipitated redissolves with difficulty. The bath is then iodized and diluted to the strength of 35 grains per ounce in the ordinary manner.

These instructions having been imparted to Mr. P. le Neve Foster and myself early in February last, we had to encounter a practical difficulty in conducting experiments at a season of the year unfavourable to sunlight exposure, and hence the delay in furnishing our report. Nitrate of silver in the proportion to make two 20-ounce baths was, however, dissolved and exposed uninterruptedly for seven weeks (including thirty-five "fair" days) to such light and sunshine as was presented to us. One portion was diluted and tried in Mr. McLachlan's presence, on the 3rd instant, with very good success; three plates being exposed that afternoon, all of which developed "clean," and the sensitiveness was in no way impaired. Mr. McLachlan objected to my using the second bath, on the score of my having added the alkali somewhat incautiously and in too great excess. This solution slowly changed red litmus to blue, but on carefully replacing the acid (dilute nitric) I subsequently produced with it some fair negatives.

Now, with respect to the bath which gave us at once such satisfactory results, I have to explain that it was mixed intentionally with a small proportion of chloride of sodium (1 grain) added to the distilled water in which the nitrate of silver to the amount of 700 grains was dissolved. My object was to ascertain by direct trial the efficacy of the action of nascent chlorine, which I believe constitutes the fundamental and only new feature of Mr. McLachlan's scheme. This suggestion, if supported by the further particulars which that gentleman has promised shortly to give, will then turn out to be a practical realization of M. Balard's chemical reaction, which, eight years ago, I had the honour of confirming in its photographic connection, and of fully describing in a paper "On the Composition of the Photographic Image," inserted in the *Philosophical Magazine*.\* When exposing to sunlight finely-divided chloride of silver in presence of an excess of the nitrate, I showed that, whilst nitric acid was liberated, *free hypochlorous acid was generated*. This body is known to be a powerful oxidizing agent; it is, in fact, the active component in bleaching-powder, and its production in an old silver bath giving "foggy" results would be an excellent method of ridding it from many dissolved impurities, and especially those of an organic nature. The same agent would be useful in a new bath as a means of guaranteeing immunity from the admixture of nitrite of silver, which I find to be occasionally present in samples of the fused nitrate. Thus we have, by this combined treatment with nascent chlorine and sunshine, a powerful means of effecting the destruction of a variety of impurities, and its use is certainly worthy of trial in the coming season, besides the recent proposal of Mr. F. Johnson to employ the permanganate of potash, and of Mr. Rejlander's system of *continually* sunning the bath without any chemical addition. A solution of hypochlorite of silver may, if preferred, be separately prepared (by shaking up oxide of silver with chlorine-water) and added to the bath, and the traces of free nitric acid, usually present, may be depended upon for liberating the hypochlorous acid.

In afterwards neutralizing the bath with dilute alkali, according to Mr. McLachlan's directions, of the *two* free acids in solution the nitric would be the first to unite with the alkali, and the proportion of hypochlorous acid outstanding would in ordinary cases be so small that no adverse action in prolonging the exposure need be feared, whilst its presence would act beneficially in restraining the development, and so producing clear pictures.

I conclude by quoting a short extract from my paper of March 1860:—

"The fact of chlorine being evolved during the decomposition by solar agency of chloride of silver under water, has been repeatedly observed and is fully corroborated by my own experiments. It follows, therefore, that if a solution of nitrate of silver be employed in conjunction with the chloride, as in the ordinary practice of photography, the evolved chlorine will exert its own peculiar action on the silver solution in contact, precipitating from it an additional amount of white chloride, which in turn becomes, partially at least, decomposed by light. It has been assumed that *the whole* of the nascent chlorine is thus available for the formation of new chloride of silver; but this can, I think, be true only if other matters are present having the power to decompose hypochlorous acid, a product always formed to the amount of *half* that of the available chlorine, according to the reaction first pointed out by Balard.

"It might then be predicted that by exposing pure white chloride of silver under a solution of the nitrate of known strength, this latter would become continually weakened. This I find to be the case; and in the event of employing a dilute solution every trace of silver is removed, leaving only mixed nitric and hypochlorous acids as residual products

\* Vide *Philosophical Magazine* for March, 1860.

dissolved in the water. It is possible also to remove the metal from a solution of nitrate of lead, by exposure to sunlight in contact with recently precipitated chloride of silver."

Woolwich, April 18th.

### A MODIFIED HONEY PROCESS.

BY G. ROBERT FITT.

THE season for out-door photography having now commenced, I have thought it not inopportune, seeing the variety of dry and preservative processes which engage, at this period of year, the attention of photographers, to call attention to one of the latter class which seems to have fallen into desuetude.

Knowing, as I do full well, the capabilities of the process, I am anxious to see a more extensive use made of it, as I am convinced that under circumstances where a dark room is accessible twice in (say) twelve to eighteen hours, no method can compare with this in certainty, in sensitiveness, or in beauty of result. I must, at the outset, disclaim any originality or claim to invention, as will be seen further on; anything I can say must have weight only in so far as that I have been, in times past, perhaps more extensively acquainted with the practical working of the method I now, as it were, reintroduce, than any photographer now living, I having employed it exclusively during two photographic seasons—1856 and 1857—for producing a very extensive series of stereoscopic and 11 by 9 views during my residence in Edinburgh.

The process, as many of the older hands amongst us will remember, is one advocated and practised by my late lamented friend, Mr. G. R. Berry, of Liverpool; and when, in 1856, I was elected on the council of the then Liverpool Photographic Society, being much in communication with Mr. Berry, I was led to experiment with it. I found it so valuable that I unhesitatingly adopted it, and perhaps carried it out further even than he did; for his mention of it to me and to our friend, Mr. Thomas, of Liverpool, an enthusiastic amateur, was less as a preservative process than as an acceleration of the ordinary wet collodion process; and this is one of its great recommendations, viz., its extreme sensitiveness, the application of the preservative to the wet plate diminishing the necessary exposure to the extent of one-half or more.

It will be remembered that Mr. Berry was one of the first to recommend the employment of bromides to any extent in collodion, and although I had myself employed them so early as 1854 with great advantage, I had not, as a rule, ventured on more than half to three-fourths of a grain per ounce of collodion. Mr. Berry, at the time (October, 1855) when I had the pleasure of making his acquaintance, was experimenting with far larger proportions, and also, I believe, with collodion containing bromide only—of calcium, if my memory serves me. It was his opinion that the preservative was successful, or perfectly so, only with collodion containing bromide, and my own rather extensive researches into the matter in the two subsequent years tended to confirm his opinion. I remember putting to him the question: "Is it applicable to all collodion?" His reply was: "Not all; it won't do with Thomas's;" Thomas's of that day being, I believe, purely *iodized* collodion. At all events, I can say it *will do* with the beautiful preparation for iron development now sent out by that celebrated maker.

I will now state the method of working. The formula is similar to Mr. Maxwell Lyte's "Instantaneous Process" published many years since. Its essentials are a good and pure sample of honey, which is to be mixed with distilled water, so as to form a thin syrup, and sufficient nitrate of silver dissolved in the liquid to make it contain about 18 or 20 grains to the *Auid* ounce. The mixture is then poured on a small quantity of pure animal charcoal (*i.e.*, from which the earthy phosphates have been removed by digestion with

hydrochloric acid and subsequent *thorough* washing), and then exposed to the sun for a week or more, and filtered, when it will run through paper perfectly bright and clear, and may be kept, for aught I can see to the contrary, for years.

The plate is coated with a good bromo-iodized collodion—not *freshly* iodized—and having been the usual time in the bath, is *well* drained; then from a glass of suitable capacity pour on the syrup, taking care, of course, that it well covers the plate up to the edges; pour off and on three or four times, and then set up to drain on a few thicknesses of religiously clean blotting-paper. Have ready narrow strips of the same paper, and lay one in the bottom of the slide, so that the depending edge of the plate rests on it. In hot, dry weather put a pad of damp blotting-paper at the back of the plate, but smaller than the plate all round, or stains will come if it touch the edge. The exposure I have found to be, as I have said before, extremely short, seldom exceeding three seconds with a Jamini's stereo lens of 6 inches focus and  $\frac{2}{3}$  aperture, and with Ross's 10 by 8 single achromatic landscape lens, with which I used to take 11 by 9 pictures from 12 to 20 seconds, using the middle or the smallest stop according to subject (focal length 15 inches). Many times I have secured brilliant cloud effects in this way with every variety of subject; especially, I remember, a negative of Prince's Street with the Scott Monument, a glimpse down St. Andrew's Street, the Firth of Forth, the hills at and beyond Burntisland, and a peak or two of the Ochills in Perthshire, with a fine bank of cumulo-stratus clouds: this was taken from "the Mound" in two seconds. The developer was usually pyrogallie with acetic acid, and sometimes a drop of citro-nitrate of silver (if one may use such a term) in hot weather. Iron developer did not answer except in cool weather, but had we known at that time of the invaluable gelatino-iron, I have no hesitation in saying that would have been the developer *par excellence*, as its special properties could in no process have been shown to such advantage.

With common care in keeping the bath in good order, failures seemed impossible except in using a new supply of collodion; but this, read by the light of our present knowledge, is soon accounted for—the collodion had not had time to ripen. I remember once having a fresh supply from Mr. Barry; trying it—fog! tried again—fog! wrote word that the collodion was bad! went on with my old sample: everything once again right. A fortnight after I was nearly run out, so mixed some new with the old, and I got good results; and by the time the mixture was used up, the new sample was in working order. The same thing has occurred since at intervals of a year or so, until the experience gained at the International Exhibition of 1862 convinced me that no bromo-iodized collodion, even for the ordinary wet process, works at its best until a month or more old.

A slight sketch of my method of working during one year (1856) will show the capabilities of the process. I made about 300 negatives in Edinburgh during the season, and, as the old lady says, "though I say it who shouldn't," I doubt if any series of equal extent has been since taken of better or more uniformly good quality; and I say this only to show what may be achieved by this mode of working.

My "local habitation" was in "St. James' Square," near the head of Leith Walk. I had simply a sitting-room and bed-room, and in the latter all processes appertaining unto negatives were carried on. No more unfavourable place than "Auld Reekie" can well be imagined—for general views, at any rate—and all that could be taken early in the morning I so took. I used to rise at 4 a.m., and, while dressing, prepare six plates, which were carried in as many dark slides. My subjects varied from Portobello to Corstorphine east and west, and from Leith and Granton on the north to Craigmillar and the Pentlands on the south, and everything between these extremes. All my negatives were, from coating to fixing, completed in the said bed-room, much, I am bound to say, to the worthy landlady's an-

noyance, and to the detriment of the wash-stand, towels, &c. However, she survived it, and the next year saw me with a good dark room, which also was the "*locus in quo*" for another series of similar extent.

Nothing need, I think, be added to show the feasibility of the process; and when its extreme sensitiveness is taken into consideration, I think if a dark room can be got at within a few hours, it is the plan wheresoever it is important to secure rapidity of working. To him who, alas! is gone from amongst us in the prime of a useful life, and not to me, is due this practical application of Mr. Lyte's process; but having had in my own working so large an experience of its value, both in the years I mention and many times since, I have thought it well to remind your readers of another aid to manipulation which gives with ordinary care results which will in every respect satisfy the most fastidious. I shall be happy to answer any questions as to the matter through the medium of your journal.

### MR. McLACHLAN'S DISCOVERY.

BY NELSON K. CHERRILL.

MR. McLACHLAN has fairly taken the photographic public by surprise. His discovery and the manner of its announcement are alike so novel and unprecedented that societies, journalists, and readers all seem quite taken aback; every one, of course, promises to experiment and report progress, but no one seems either fully to understand what has been already advanced, or to care to venture their opinion on the merits or demerits of Mr. McLachlan's proposition. It seems even more difficult for the photographic public to take in the idea of an alkaline bath than that of a bath made with common water in the place of distilled. Of course, when an experiment takes from one to three months to perform properly, according to the inventor's own instructions, no definite answer can be given of its results before the lapse of that time. However this may be, a few words on what has been already advanced may not be out of place. Mr. McLachlan is going to read a further paper on his discovery, and then, no doubt, he will throw more light upon the matter; but as it will be nearly a month before this paper will be in the hands of the public, it may be as well to make a few remarks on what has been already advanced.

In the first place, I do not think it is by any means so certain—at least, Mr. McLachlan has not, it seems to me, set it forth as certain—that he really does recommend the use of an alkaline bath at all. I will explain. It is generally supposed that nitrate of silver is not affected by light; we will let that pass, as it is enough for my purpose that Mr. McLachlan says it *is* affected. Now, the first and most obvious effect of light upon silver salts is to reduce them to the metallic state. All must have noticed how, if the slightest organic impurity gets into the bottle in which nitrate of silver is kept, in course of time the small particles adhering to the sides will become black by decomposition and reduction. Nitrate of silver, when reduced, liberates nitric acid and oxygen—

The reason why nitrate of silver is not supposed to be reduced unless it is in the presence of some organic matter or other suitable substance is, that the equivalent of oxygen will not leave the silver unless some object be presented to it for which it has more affinity than for silver. It seems to me, however, very probable that in performing the McLachlan experiment *some* organic matter may be present, or, if not some organic matter, some trace of an inferior metal in the nitrate of silver, which, I think, would probably answer the same purpose. If, then, such is the case, an exposure to the sun for two or three months would certainly effect a slight reduction of silver, so that the solution which was *neutral when put out in the sun may very probably be slightly acid when brought in again, from nitric acid liberated in the trifling reduction of silver mentioned above.*

Now let us see the result of an addition of a solution of caustic potash. Caustic potash, when added to a neutral solution of nitrate of silver, forms at once a precipitate of oxide of silver, and the solution becomes faintly alkaline, *not* with caustic potassa, because the whole of the potassa is decomposed, but because the oxide of silver is to a slight extent soluble in water, and has, when so dissolved, a faintly-alkaline reaction.

Mr. McLachlan, when his silver comes in again from the two-months' sunning, finds that a trace of caustic potassa added to it does not produce any precipitate of oxide of silver, or that, if produced, that precipitate is at once redissolved. This seems to me to be easily accounted for. The trace of nitric acid I have mentioned as being probably formed in the solution when out in the sun would, of course, at once form, with the oxide of silver, a little more nitrate, and leave the solution either *perfectly neutral or very slightly acid.*

After iodizing, then, Mr. McLachlan dilutes the bath. And here comes a point which requires both more elucidation from the gentleman himself, and also, I think, more careful observation by others as well. We are told that after a certain time all the iodide will be thrown down, and that then it has no more power to dissolve iodide, and no further dilution can precipitate any more. I do not for a moment doubt these statements, but it is not clear yet to my mind quite how the matter comes about, whether the bath is *used* before it throws down the iodide, or whether the action is quite spontaneous and quite independent upon any external circumstances. As we have not yet had this part of the subject fully explained, I would leave it now, as it is more my object to deal at the present moment with the question of the alkalinity than with the keeping properties of the bath.

Should what I have stated prove correct, as to the bath being not alkaline, but having a trace of acid, or being perfectly neutral, it will be seen at once that the result, though gained in a very different way, will be much the same as that obtained by Mr. Thomas in his "normal" bath. He recommends the addition of oxide of silver to the bath—enough to render it turbid; then, after filtration, he adds just enough nitric acid to balance the alkaline reaction. Mr. McLachlan appears to me, on the other hand, to render the solution acid first, and then to balance this acid by a trace of oxide of silver. It may be—and I would be the last to say it is not so—a matter of great importance *how* a result is obtained. Many have, I think, noticed that a bath, especially under some conditions, works better after sunning. Thus it may prove that Mr. McLachlan's *mode* of preparing a bath, albeit the *result* is the same as we have arrived at before, is much the best that has ever been found out.

Now as to the collodion: of course, as Mr. McLachlan says, the collodion must assimilate with the bath, and it seems to me the result which is produced by adding caustic potassa to collodion in a very ripe red condition is merely to eliminate some of the iodine, and reduce the collodion more nearly to the condition of newly mixed collodion, a condition which was some time ago considered as essential to rapid work, especially when the collodion contained rather more iodides than bromides, as, from my experience with Mawson's, I believe is the case with that solution.

Caustic potassa, when mixed with iodine, forms iodide of potassium, &c.; thus it seems to me that the addition suggested to be made to the collodion by Mr. McLachlan simply adds a little to the quantity of iodide of potassium, and eliminates the free iodine. Thus we seem to have a neutral collodion and neutral bath. These conditions would give naturally the "fog" and other mess described by Mr. McLachlan when using a developer made with new good iron, but when old, the iron developer has more restraining power, and is well known to work with more cleanness and certainty, especially under such conditions as I apprehend Mr. McLachlan has recommended.

As I said before, it may be a matter of great importance *how* the result is obtained, and by virtue of going in a new, and I think almost a round-about, way to work, Mr. McLachlan may obtain a result which, though theoretically the same, or almost the same, with what has been done before in a much more simple way, may in some important respects be better.

I may sum up by saying, that though it is difficult to see *how* Mr. McLachlan's plan is better than any other for producing what seems to me a similar result, still, as there is no knowing when we may come to an end of the wonder of photography, it may be a new light has sprung up among us, and I shall have much pleasure in making the whole of the experiments carefully and reporting them when the time comes.

PICTORIAL EFFECT IN PHOTOGRAPHY;  
BEING LESSONS IN  
COMPOSITION AND CHIAROSCURA FOR PHOTOGRAPHERS.  
BY H. P. ROBINSON.  
CHAPTER XIII.

"Nature, everywhere, arranges her productions in clusters; and to this end she employs a variety of means. The heavenly bodies are grouped by attraction, flowers and trees by the natural means by which they are propagated, while the social instincts congregate man and most other animals into societies; and the same instincts impel, in man as well as in many of the inferior creatures, the grouping of their habitations. Grouping is, therefore, a universal law of nature; and though there are cases in which a scattered display of objects may, in parts of a composition, greatly aid, by contrast, the more compact portions, and cases in which scattered objects may help to tell the story, yet in the composition of a picture, taking the whole together, a scattered general effect is always a fault."—*C. R. Leslie.*

"We are very sure that the beauty of form, the expression of the passions, the art of composition, even the power of giving a general air of grandeur to a work, is very much under the dominion of rules. These excellences were, heretofore, considered merely as the effects of genius; and justly, if genius is not taken for inspiration, but as the effect of close observation and experience."—*Sir Joshua Reynolds.*

Any very obvious geometrical form, either in masses of light and shade, or bounded by lines, would necessarily be a defect of arrangement; but a certain degree of regularity, such as that arising from a proper appreciation of the rules of composition, and resulting from the concentration and grouping together of the parts, is undoubtedly greatly to be preferred to that kind of irregularity which would be made apparent by the promiscuous scattering of objects over the plane of the picture.

It may be objected that few landscapes will fall into these convenient forms for the benefit of the photographer. This I am quite ready to admit; but when he is acquainted with those forms that are known to produce picturesqueness he will be ready to take advantage of accidents of position and of the various effects produced by light and shade at different times of the day. Besides, forms of objects alter with the point from which they are observed. Twining, who has written a readable if not very practical treatise on the philosophy of painting, says:—"Form itself depends, in a great measure, on the position selected by the observer, on the direction of the lights, and the transparency or mistiness of the atmosphere. From such causes as these the mountains may become more elevated, the plains more vast; depth, space, and distance may be increased; and the artist, who thus adds to the grandeur or beauty of a subject, by availing himself of means borrowed from nature herself, instead of tantalizing the mind, and engendering an admiration based, in a great measure, on ignorance in matters of art, instructs, at the same time he diverts, his admirers." This is equally true for the photographer as for the painter.

But if the landscape will not arrange itself at the photographer's bidding, he has more power and command over his materials when his subject is a figure or a group. If he be not perfect master of the expression of his sitter—and some photographers show by their works that even that is possible—he has in his hands the possibility in a very great degree of governing the disposition of the lines and the

light and shade. If he find several lines running in one direction he has the opportunity of altering the position of the body or the drapery so as to create opposing lines, and he has great scope in the artistic arrangement of the accessories and background in preserving balance, either by lines, or light and shade; and yet how often are these advantages neglected, or, rather, how very seldom are they employed! For many years (and, indeed, to a great extent at the present time) a plain background without gradation was looked upon as very successful work, and nothing but insipid and monotonous smoothness was aimed at by photographers, with the exception of those who already had a feeling for the picturesque, or those who were not too proud to take a lesson from the works of others. It is encouraging to see that many photographers are alive to the necessity of doing something more creditable to the art; and the many imitations that have lately been shown—although few of them have yet risen above the level of mere imitation, or at all approached the great originals—of the productions of that photographic Rembrandt, M. Adam-Salomon, give indication that some improvement may be expected.

It is always well, when possible, to teach by example, and I append an outline of a well known portrait, of which

large quantities have been distributed, chiefly because of the celebrity of the subject, and partly, no doubt, because of the excellence of the technical qualities. I do not indicate this individual picture more distinctly, because I think that when I feel compelled to use any particular photograph as "an awful example," it is scarcely fair to the author to mention his name, although my remarks would be more easily understood if the original could be placed before the student instead of an outline wood-cut.

It will be seen that most of the lines, although not parallel, run in one direction. There is no balance whatever, no variety of lines, no relief, and the space behind the figure is "to let." There is no employment for so much space, except to make the picture the regulation size. The background in the original is perfectly plain—one unbroken tone from the top to the bottom. You see any part of the picture as soon as, or before, you see the head, and the figure appears to be inlaid, or sunk into the background. It would have taken no trouble to alter all this if the operator had possessed a sufficient knowledge of the requirements of art, and, what is quite as necessary when engaged with an eminent sitter, the presence of mind to use it.

This, or a similar position, more full-faced, one hand on a table and the other on the knee, is to be seen in nine out of every ten photographs of the sitting figure; in fact, it appears to be the traditional position of the photographic sitter handed down from the earliest times, and religiously followed by photographers who are not observers, or who do not know how to invent positions for themselves. But, supposing it necessary to maintain the figure in nearly the same position as that in the sketch, what should have been done to produce a more agreeable composition? A very slight change in one of the accessories would have done nearly all

that was required. At present the lines run nearly in the same direction, without any opposing lines to balance them, and there is a space behind the figure that requires filling, while the table and vase carry the eye out of the picture to the left, and overcrowd that side of the composition. If the table had been moved to the right side of the picture, stability would have been given to the figure; the numerous weak and almost similar curves of the figure and chair would have been opposed by the straight lines of the table, the space that was to let would have been filled, the lines of the figure would have been properly balanced, and the table, which crowded the left of the picture, would be doing service to the general effect, and the figure, although turned slightly away from it, would still have the effect of being seated naturally near the table; while, if some attention to light and shade and gradation had been observed in the background, everything would have been brought into harmony. There is another defect which should be carefully avoided: the curves of the chair-back exactly follow the curves of the arm.

As a contrast to the foregoing, I introduce a little sketch by Sir Noel Paton, in which it will be observed that balance

has been strictly considered, and the figure is admirably supported. Notice how the lines of the leaning figure are contrasted by those of the arms, and, for fear these should not be sufficient, two trees have been introduced to perform the same function in the composition. And the hat and plants on the ground perform the part of the point of dark so often mentioned in the chapters on landscape.

This simple little figure illustrates much that is valuable in art, and I shall probably have to refer to it again; at present it has answered the purpose for which it was here inserted, that is, to show the difference between a figure represented "just as it sat," and a picture produced by one who conforms to the rules of art.

#### PHOTOGRAPHY APPLIED TO MECHANICAL PRINTING PROCESSES.

BY R. GRIGGS.\*

IN compliance with a request from our esteemed Secretary, I have the honour to place before you a subject, the importance of which, I think, cannot be overrated; namely, the application of photography to ordinary methods of printing; and I have thought it better to divide the methods of printing into chemical printing, or lithography, and type printing, dealing only with the first this evening, leaving type or surface-printing for another occasion; and in adopting this course I must of necessity be brief, for it is not possible to do full justice to such a subject in one evening meeting like this, because I am desirous, as far as time will allow, of practically illustrating to you the method I have adopted

to obtain these photo-lithographs, in eight colours, which Dr. Forbes Watson, the Chief of the India Museum, has placed in the hands of Dr. Diamond, your Honorary Secretary, for presentation to each member of this Society. A short *resumé* of the various steps which have led us to the useful yet infantile point, we now find photo-lithography, will not be out of place before proceeding to details. The invention of chemical printing, or lithography, was the invention of a German, Alois Senefelder, in the year 1795, who, while in search of a cheap means of printing his dramatic productions, by an accident discovered that, by writing on a piece of Kolheine stone with a greasy ink, a surface could be obtained from which prints could be easily taken, either in one or several colours, and obtaining effects unreached by wood-engraving.

The establishment of the art of lithography in England is due to Hulmandel, who greatly improved the processes for obtaining the different class of drawings from one or several stones, and printing from them in colours. The effect thus obtained advanced the art, and increased the facility for producing artistic effects. I need not enumerate the many workers in this important field, from the time of its introduction into England to that when we find the productions of Owen Jones and Francis Bedford appearing before the public as splendid examples of artistic feeling. As I do not intend these remarks to be anything like an exhaustive essay on this subject, neither do I intend to argue to whom the honour belongs of connecting photography with lithography, as to whether he was an Englishman, a Frenchman, or a German; but I feel bound to say that the name of Osborn should be connected with the wedded life of photo-lithography, not only on account of his early productions, but on the good results he has produced; then the names of Talbot, Poitevin, Ponton, Archer, and Diamond ought to be mentioned, for having provided us with the results of their important discoveries of the application of collodion, potash, gelatine, and pigments, without which photo-lithography would not be in the position we now find it. Although it has had to contend against many selfish elogs, in the disguise of patents, which have been taken out since then to block the path of progress, it has advanced to the splendid position of making the past subservient to the present, by giving us the means of faithfully reproducing, in permanent printing, those interesting manuscripts which give such insight into the manners and customs of those who have preceded us, as well as the beautiful designs which adorn the many public museums and libraries. Our Secretary, since the last meeting, has furnished me with a drawing, from which I have produced a block, which I beg to hand to you for your inspection, and I propose to transfer a copy of the same drawing to stone this evening, and print from it before you, as well as pull a few copies off the stones from which the presentation prints have been taken; and when I tell my commercial friends that these have been produced at less than one-half of the price that these would have cost if entirely done by hand, I feel that I indicate to you a field which is full of promise to the enterprising photographer.

The first important step is to obtain a negative free from deposit on the lines of the subject copied, and moderately dense; it will give the best results if used unvarnished, in consequence of the contact being better than when a film of varnish intervenes between the negative and the prepared paper. The method of preparing the paper is as follows:—Put 1 pound of rice starch into a large bason, and dissolve into a stiff paste, by the aid of a large spatula, using as little cold water as convenient; into a saucepan put half a gallon of water, boil, add half a pound of plaster of Paris, then pour it gently on the paste, which must be kept well stirred till the whole of the water has been added; it should now assume the form of a tremulous jelly; place (say) a dozen sheets of Saxe paper at a time on a board, and with a large brush cover the paper with a thin and even coat of the above. It will be as well to use up the whole of the starch, for the paper may be kept any length of time, and will always be ready

\* Read before the London Photographic Society, Tuesday, April 14th.

for the next operation of coating it with gelatine, made by soaking 1 pound of gelatine in cold water the day before you want to use it; throw away the water not absorbed in the gelatine; wash it well; do not be afraid of washing it, for should any dissolve, by all means throw it away, for it would only be a source of trouble if retained. Now add 1 drachm of ammonia, which will carry down the phosphate of lime contained in most gelatine, in consequence chiefly of the admixture of bone with the tissues in its manufacture; dissolve on a water-bath, then add 1 ounce of sugar; strain through warm wet flannel or fine muslin. In coating the paper, various ways may be employed, either by floating it on the warm gelatine contained in a flat dish, or the gelatine may be floated on plate-glass, and then, as soon as it is set, laying damp paper down on it. This would be a good way of coating the paper were it not very slow, for you cannot depend upon getting it ready under two days. I have employed a machine for coating paper which is much too large and clumsy for me to show you here; but, as I intend making a smaller one, suitable for Saxe paper, I shall have pleasure in explaining it on some future occasion. Here is some pigment paper for pigment printing, which process I have completed by camera-printing, doing away with the troublesome transferring necessary in the usual way of carbon-printing. It can be produced by it at a very rapid rate, but for limited lithographic work it is not necessary. The paper prepared as above can be kept in stock like aluminized paper, requiring only to be sensitized by immersion in a saturated solution of bichromate of potash, when it will be ready for printing. With an average intensity of light it will take about five minutes to print, after which it should be immersed in cold water for about a quarter of an hour. Get ready some retransfer ink, rubbed down rather thin with turpentine. Here is the kind of ink I prefer; blot off excess of moisture; then, with a sponge, rub over the print with the transfer ink; then clean the lights of the picture with a sponge moistened with weak nitric acid and gum-water; after which it must be well sponged with clean water. Give the transfer three or four hours' rest, to allow the gelatine to harden in the light. It is then placed on the surface of a clean lithographic stone, either polished or grained, according to the nature of the work; it is then passed through the press. On examining it you will find it adheres very firmly to the stone; the back is now damped with a wet sponge to loosen its hold on the stone; after the paper support is taken away, the picture is gummed in and rolled up with printing ink; it is not yet safe for printing; for although the stone contains gum between the ink-lines of the picture, and theoretically ink will not adhere where there is any gum, yet, in course of printing, the great scraping pressure given to obtain the prints would cause the lines to spread; this is prevented by etching the stone with weak nitric acid, after which it is difficult to get even transfer-ink to adhere, if you wish to make any addition, without scraping the surface acted on by the gum and acid. We have now come to the point where we find this stone, which is the key to all the rest; as many prints are now taken as there are colour stones to be made up on well-rolled paper, the least likely to stretch, then dusted over with powdered red chalk, each laid on a separate stone carefully passed through the press; there will then be a facsimile of the keystone on each of them, which are filled up by hand; where required, several stones can be made by retransferring portions of the keystone. With this subject of eight printings, the keystone is the one used to represent the threads of the material, the set-off of which has only to be filled in solid to make the gold-stone, and so on through the various printings. This is photo-lithography proper, but it is not the only part that photography plays in connection with lithography. Here are some subjects obtained another way. I wish I could have shown you the original drawings from which these were taken, for you to see the truthfulness of their reproduction. When you see these numerous portraits, in some cases numbering over in

each picture, and every one of them an exact facsimile, you will, I think, admit with me that it would not be possible to do it entirely by hand with the same truthfulness, unless it is accompanied by a great expenditure of time and money, bearing in mind that they are all either enlargements or reductions; therefore the ordinary means of using tracing-paper will not do. The way I have adopted is this: I take a reversed negative of the subject; this gives a reverse print; in other words, it is in the exact position required for the stone; it is now used as a tracing. If we place a piece of retransferring paper (made by rubbing red chalk on thin paper) under it on the stone, we have but to go over it with a metal point to obtain the picture in chalk on the stone; it is now ready for the artist to work on with his brush. There is another way of obtaining the picture on the stone; and if I am not greatly mistaken, some prints I have seen lately from "a new process of photography on stone" have been produced by the same means I employed some four years ago by coating a grained stone with silver, and printing with the negative direct on the stone. We have the picture, which requires only to be worked over with the crayon, and thus obtain the fair results which, I dare say, some of you have seen.

Now, gentlemen, I have given you an outline of the way in which the art of photography can and has been linked with a rapid and permanent means of printing, thus diffusing a knowledge of ancient art which would have remained in the dark receptacles necessary for their preservation unknown and unnoticed, except by the book-worm. In collating these few remarks, I make no claim to any new discovery, but must give my humble tribute of thanks to those pioneers of true progress in our art who have not selfishly kept back useful information, or prided themselves on secret dodges, but have come before this and kindred societies, giving freely the results of their labours. I used the word "rapid;" perhaps, when you see the printer at work presently, you will think it is rather slow than rapid; but the application of steam-power to lithographic printing is now making a complete revolution in this method of printing. Here is a specimen which a Conisbee machine has printed off at the rate of 800 per hour, or 8,000 per day; and when I show you the means of retransferring or multiplying any design when required on ordinary-sized paper for bookwork that can be printed in sets of four or eight, you will see at once that a new era is opening for lithography, and, as a matter of course, for photo-lithography. I will now proceed to work, after which, if there is any question any gentleman may wish to ask, it will give me great pleasure to answer it.

#### REMARKS UPON THE CARBON PROCESS.

BY DR. H. VOGEL.\*

SWAN'S carbon process has been the subject of universal attention during the past summer. The paper and chemicals manufactured by that gentleman have been introduced into Germany, as likewise those produced by Rowell, of Boston; and an opportunity has thus, for the first time, been afforded to practical photographers to experiment with the process without the expenditure of very much time and trouble. Many photographers have availed themselves of this opportunity, and from almost every side correspondents have sent us communications, questions, letters, and details of successes and failures. The interest thus evinced on every hand has induced me to make a further investigation of a field already somewhat known to me, and the practical experiences thus gained I now publish, trusting that those operators who may have experienced difficulties in the manipulation of the process may obtain some information from my observations.

Two considerations exist at present against the practical introduction of the carbon process; they are, the high price

\* Read before the Berlin Photographic Society.

of the materials employed, and the complicated form of several of the operations. How long these objections will remain in the way time alone will show. The process possesses, however, several important advantages, the greatest of them being the extraordinary sensitiveness of the carbon paper. In summer, during favourable weather, this quality is not so apparent and striking as in the foggy November weather. On a dull November day, when a silver print is scarcely sufficiently printed if exposed from morning till evening, I have been able to obtain an over-exposed carbon print from a negative of average thickness in sixteen minutes and a half, and in nine minutes and a half a remarkably vigorous carbon print from one of Loescher and Petsch's portrait negatives; and this with carbon paper which was by no means of the most sensitive description, but which, under thick negatives, required to be exposed up to 18° of the photometer scale, and with thin plates up to 14°; with paper prepared by myself, I need not expose further than 15° for a thick, and 11° for a thin negative.

This sensitiveness of the carbon paper is a matter of considerable importance in commercial photography, especially when work is carried on on a large scale. If, for instance, the production of a thousand copies were required from one carte-de-visite negative by means of the silver process, the time required for printing the same would be about fifty-six days, or nearly two months; with the carbon process, which is at least eight times as sensitive as the silver method, the thousand pictures might be turned out in the space of seven days.

In the course of last month I made a series of observations with reference to the best method of effecting the transfer of photographs upon glass, suitable not only for the carbon process, but for other methods, such as photo enamelling, &c.

One of the principal points to be attended to, mentioned by Wilson in his article on carbon printing, is to prevent the formation of air-bubbles in the paper during the operation of developing. Freedom from these imperfections may be secured by the very simple precaution of allowing the carbon print fastened to the india-rubber paper to remain for a short time in cold water previous to development. The formation of bubbles results from the presence of air in the pores of the india-rubber paper: if the latter is immersed suddenly in warm water, the air expands quickly, and swells into bubbles under the film of india-rubber; but if the papers are first placed in cold water for a short time (the india-rubber paper uppermost), the air is gradually expelled by the water in minute globules. After remaining thus for a quarter of an hour, the paper may be transferred to a warm water bath, where the picture is detached and developed.

The prior immersion in cold water possesses another advantage: it removes the chromate from the paper, which thus becomes insensitive to light, and allows the development of the picture to take place in the daylight, by which means this important operation may be more successfully controlled.

The developing process I have already described in a former communication. After the picture has been fully developed the paper is rubbed over with a brush, to remove any superfluous carbon particles; and it is then dried, and coated with gelatine. During the last-mentioned operation the formation of minute bubbles often occurs, especially at a cool temperature; but these are easily removed by the application of the finger.

Wilson recommends the transfer of the picture to Steinbach paper, but this operation does not finish the process, as the print must afterwards be mounted upon cardboard. Instead of this, therefore, the picture (as Mr. Swan informs us) may be transferred direct to cardboard, provided the latter presents a perfectly white and even surface. The mode of proceeding is as follows:—The card is placed for the period of one minute in cold water, then pressed between sheets of blotting-paper until it ceases to shine, but appears almost

half dry, and the picture (previously gelatinized and trimmed) laid upon it; both are then placed between pieces of felt and pressed in a rolling-machine, the picture being undermost. Finally, the india-rubber paper is removed with benzol. In operating in this manner it is indispensably necessary that a good cardboard with an even surface should be employed.

Both methods of transfer are, however, open to an objection. The delicate outlines of the picture are easily damaged in the event of the paper being too moist, for the gelatine gives way and the roller injures the softer details of the print. For this reason Cherrill employs a press instead of a roller, and the mode of proceeding detailed by him in a recent article I have found to answer admirably. For small pictures an ordinary copying-press will be found sufficiently powerful, but in this case the pictures must be so wet as to shine. Blotting-paper is laid upon the picture, which is allowed to remain under pressure for about four minutes, and then taken out and dried. By this means it is impossible to damage a picture.

Another interesting idea Mr. Swan has communicated to me: the picture upon the india-rubber paper is immersed completely in a warm gelatine solution of—

Gelatine...	...	...	...	6 to 8 parts
Glycerine	...	...	...	2 to 2½ "
Water	...	...	...	100 "

and when all air-bubbles have disappeared, a piece of fine tracing-paper is likewise immersed in the solution, and both are then removed, care being taken to allow them to draw over the side of the dish, in order that they may be properly drained. Both are hung up to dry, trimmed, placed upon moist cardboard, and put through the rolling-press without any fear of the print being injured by the pressure; the india-rubber is afterwards removed with benzol. This process I have worked with very good success. If the picture upon the india-rubber has been covered with a thick coating of gelatine (with 12 per cent. of gelatine), it can be detached, after moistening with benzol, in the form of a clean film.

This circumstance led me to experiment upon the feasibility of transferring the carbon print to glass—an operation in which I was perfectly successful. For this purpose I coated the picture upon the india-rubber film liberally with the following solution:—

Gelatine	...	...	...	12 parts
Glycerine	...	...	...	4 "
Water	...	...	...	100 "

and fastened it upon a warm glass plate; the transfer was then allowed to dry, and then the india-rubber coating removed with benzol. The picture remained upon the glass plate in the most perfect state. It is as well to coat the picture on the back, before it is dry, with a solution of—

Chrome alum	...	...	...	1 part
Water	...	...	...	300 parts

In the same manner pictures may be transferred to opal glass, and in this form have a very pretty effect. For the enamel and porcelain processes the method is likewise susceptible of application; an enamel colour is mixed as the pigment in the carbon-tissue, and by this means a transferable picture is obtained, capable of being burnt into any suitable surface.

Another interesting circumstance I may here point out. In the picture upon glass we possess obviously a carbon positive, and, by a repetition of the process, a carbon negative may be obtained. Here is therefore a method of multiplying negatives, and of producing them of a more permanent character than by means of the silver process.

Since writing the above, a result of some importance has been obtained in the photographic laboratory at the Royal Industrial College, which will interest those who have experimented with the process. One of my pupils, M. Lother, a student in the College, was proceeding in the ordinary manner to transfer to Steinbach paper several developed carbon prints upon india-rubber paper; by an oversight, he

omitted to coat the print with gelatine, but pressed the dry india-rubber picture direct upon white paper, treating it with benzol in the ordinary manner after it had become dry. To my astonishment, the picture became detached in the most perfect manner, and I proceeded at once, therefore, to repeat the experiment. A few more carbon prints were prepared and developed, and, when dry, placed upon pieces of moistened white paper, subjected to pressure, again dried, and treated with benzol; this second experiment was likewise remarkably successful. The washing off of the india-rubber was a much easier operation than when gelatine was employed, and the pictures obtained were of a finer and more brilliant description. From these experiments, therefore, and from further trials made in the same direction, it is to be inferred that the treatment of the developed carbon print with gelatine, and the tedious operation of preparing the gelatine solution connected with this branch of manipulation, is a perfectly superfluous proceeding; the considerable amount of time and labour thus gained cannot be estimated too highly. At eleven in the morning the pictures were printed, and at four in the afternoon they were ready for delivery.

I shall be glad to be informed of the experiences of any operator occupied with the process who may feel inclined to repeat my experiments.

## Proceedings of Societies.

### AMATEUR PHOTOGRAPHIC ASSOCIATION.

A COUNCIL MEETING of the above Society was held Monday, April 6th, at 12, York Place, Portman Square, the Right Hon. the Earl of Caithness in the chair.

The minutes of the last meeting having been read and confirmed, the following members and subscribers were elected:—Capt. W. Forster; W. Baily, Esq.; P. M. Jackson, Esq.; Mrs. J. Cook; T. Samuels, Esq.; R. Grace, jun., Esq.; R. Leigh, Esq.; E. Milsom, Esq.; M. W. Wemyss, Esq.; E. Horner, Esq.; J. Richardson, Esq. The Secretary then laid before the Council the following prizes, which were fully approved by the meeting:—Five silver goblets, five silver-mounted claret jugs, a coffee-pot, a revolving stereoscope, and seven large photographic albums, whole bound morocco, with silver plates.

The CHAIRMAN then proceeded to sign the certificates of honourable mention, twenty-three in number; after which the Secretary called the attention of the meeting to some specimens of the series of portraits entitled "The British Museum of Portraits," which for the past three years he has been taking under the auspices of the Council of the Association; and after some discussion it was proposed by Mr. GLAISHER, and seconded by the Right Hon. the Viscount RANELAGH, that the Secretary should wait upon Henry Cole, Esq., relative to the transfer of the portraits to the South Kensington Museum. The proceedings then terminated.

A. J. MELNISH, Hon. Sec.

## Correspondence.

### "LUX GRAPHICUS" ON THE WING.

OXFORD AND CAMBRIDGE—CABINET PORTRAITS—MR. McLACHLAN'S SECRET.

DEAR MR. EDITOR,—Do not let the above heading alarm you. I have no desire to convert the columns of your valuable Journal into a kind of photographic *Bell's Life* or *Sporting Chronicle*. Although the great University boat race has just been decided for the eighth consecutive time in favour of Oxford, it is not of that aquatic struggle that I am going to write, but of another matter in which the Cantabs seem to be behind the Oxonians in the race of life, or the pursuit of novelties. Not only are the Cantabs short in their stroke with the oars, and unable to obtain the first place in the contests on the Thames, they are also slow in giving their orders for a

certain article of commerce which is of very great importance to professional photographers, especially those in the neighbourhood of the University of Cambridge. It is a remarkable fact, that while Oxford has gone in with a rush for those very charming portraits technically named "cabinets," Cambridge holds aloof. How is this, I wonder? There are as good photographers in Cambridge—Mr. Mayland, to wit, whose work is all of the first class—as in Oxford; the sun shines as brightly in the region of the Cam as he does in that of the Isis. Have the Cantabs made up their minds not to be *cabinet* men in opposition to Oxford? or is the fact due to the lukewarmness of the Cambridge photographers themselves? It seems somewhat strange that two places likely to be so similar in tastes and a refined appreciation of the beautiful should so differ in this respect. Are the men of the two great seats of learning in this country opposed in matters of photographic proportion as they are in other matters of minor importance—as in the proper pronunciation of either and neither, for instance? Not having graduated at either, I do not know which is correct, neither do I care; but I am concerned in this question of photography. While at Oxford the cabinet picture has taken deep root, and has grown into a strong and vigorous article of demand, it is a well-known fact that at Cambridge it is "sicklied o'er with the pale cast of thought," and languishes on in a state trembling between life and death. Whether the producers or consumers are to blame for this languor in the demand for an article that is certainly worth being cultivated, is more than I can say. I know that the discrepancy exists, and the rest I leave to those most immediately interested. It cannot, however, be supposed that a demand for any particular size or style can spring up spontaneously; that must be created by the producer, by popularizing the style in some attractive and judicious manner, and the cabinet size is well deserving of a very strenuous effort being made in its favour.

Of all the photographic sizes that have been introduced to the public the cabinet is the most artistic in its proportions. As nearly as possible it falls under that art rule of producing an oblong or parallelogram of the most agreeable proportions, which is as the diagonal is to the square. The size of the cabinet is 5½ by 4, and if you measure the diagonal of the square of 4 inches, you will find that the length of the cabinet, 5½ inches, is as near that as possible. Doubtless Mr. Window had this in view when he introduced the size, and, whether for upright or horizontal pictures, such proportions are decidedly the best. Many of the sizes already in use are too long, others are too short and square. In addition to the beautiful proportions of the cabinet size, it gives the portrait photographer more room and opportunities to introduce harmonious forms and effects in the posing and arrangements of portraits and groups; and I have seen some very charming views on the cabinet size, 5½ by 4 inches, horizontally; as well as some very beautiful interiors of Westminster Abbey, by Mr. V. Blanchard, on the cabinet cards vertical, which proves pretty conclusively that the proportions of the diagonal to the square of any size will suit both vertical and horizontal pictures. I have not the least doubt but a much greater demand for those cabinet pictures, both portrait and landscape, could be created, if photographers would set about introducing them with a will; depend upon it if they will but put their heart into the matter, they would put money into their pockets. I know how much has been done by launching them fearlessly on the sea of public patronage in several localities, and I feel certain the demand would be much more general if the cabinet picture were judiciously introduced. Mr. H. P. Robinson and Mr. Nelson K. Cherrill, having entered into partnership, are on the point of opening a photographic establishment at Tunbridge Wells, where they intend to incur considerable expense to introduce the cabinet portrait, and give it that prominence it so justly merits.

Since writing you last, I learn from a friend who is intimate with Mr. McLachlan that there is every possibility of his secret being revealed ere long. That this secret formula will be an immense boon to all photographers, there can be little doubt.\* If an absolute immunity from streaks in the direction of the dip, brain-markings, and pinholes—which are the advantages said to be derived from the process—can be guaranteed, then will the manipulatory part of photography be at once made easy; and Mr. McLachlan will have conferred a personal obligation on every photographic manipulator. Not only will photo-

\* This letter was received before the meeting of the Photographic Society.—Ed.

graphers be benefitted by Mr. McLachlan's generous conduct, the whole world will participate in the advantages he intends to place as a gift in the hands of photographers; and even art, that is so afraid of a photographic amalgamation, will be honoured by the revelation. But once let the mind of the operator be for ever free from the cares and anxieties of his negative being clean, spotless, and excellent in quality, he will then have more time and inclination to put his art knowledge, if he have any, into practice, by paying more attention to the pose of his sitters and the artistic choice and arrangement of accessories. If he be without art-knowledge he will be obliged to acquire it and put it into practice, or be driven out of his field of operations. For, if the chemical difficulties and uncertainties are to be so summarily disposed of, and all the manipulations reduced to a certainty and dead level, a pre-eminence in the profession can only be maintained by him who exhibits a taste, feeling, and love for his labours superior to the desire to palm upon the public, for mere gain, works that are a disgrace and a scandal to the profession of which he is a member. That such a condition of things photographic may be quickly brought about is much to be desired, and if such be the result of Mr. McLachlan's very noble willingness to give to the photographic community experiences that have cost him much time and money in acquiring by close observation and experiment, he will, at the least, be entitled to the sincere and hearty acknowledgments of all well-wishers and lovers of our art-science.

*Apropos* of clean and easy development, I should like to know if any of your numerous readers have tried the effect of sulphate of zinc with the iron developer. I understand its use obviates the necessity of using acetic acid as a retardant; that the deposit of silver is much more delicate than that produced by iron alone; that the control over it is very great; that any amount of intensity can be obtained by one or more applications, without the aid of pyrogallie acid, and without producing harshness or hardness. With such recommendations it is certainly worth a trial. I have had no time to try it myself, but think it is of sufficient importance to give your readers an opportunity of experimenting with it, and judging for themselves.—Yours very truly,

LUX GRAPHICUS.

April, 10th, 1868.

## Talk in the Studio.

**PORTRAITS WITH NATURAL BACKGROUNDS.**—Since our notice of the charming artistic portraits of Mr. Edge, in which a pictorial background obtained from natural scenery was introduced, we have seen several praiseworthy attempts in a similar direction. A short time ago Mr. Burgess, of Norwich, sent us an example in which the natural background from a second negative was most successfully introduced. We have just received a packet of portraits "produced in the ordinary course of business" by Messrs. Robinson and Thompson, of Liverpool, in which this method of working is carried out with great success, and is manifestly, from the wonderful variety of effects, worked on a tolerably extensive scale. We have upwards of a dozen portraits, in every one of which a different scene is introduced for the background. Many of these are charming portraits of nice children, whose costume and occupation harmonize admirably with the scenes. Here is a bright intelligent little fellow trudging through the furze with his gun; and next we have him with the piece rested upon a large boulder, sighting his game. In another the same little urchin is stretched upon the grass overlooking a stream. In others a pretty little girl with a basket full of wild flowers rambles or rests among pleasant scenery. In all cases the varied landscapes join admirably with the foregrounds, generally composing well, and retiring sufficiently to give atmosphere without fog. We understand that many of these examples excited much interest at the recent soiree of the Liverpool Society. We are glad to see the brother of Mr. H. P. Robinson following his example, and excelling in combination printing and art photography.

**LONG EXPOSURES IN LANDSCAPE PHOTOGRAPHY.**—A correspondent signing "Gladiator" sends us a long letter on this subject. After some trenchant remarks on a communication which has appeared in other pages, and to which it is not

necessary to refer further here, he says:—"As to the question of 'truth to nature,' I confidently assert that, as a rule, long exposure gives a false representation of nature, the reasons being simple and obvious. A landscape is taken under certain conditions of light: if a long exposure be given, those conditions will be materially altered; in sunshine the change would be rapid, the shadow from each object changing with the course of the sun, so that what is light one minute becomes shadow next. An exposure of 90 minutes would simply produce a muddle of light and shade, truth to nature being sacrificed. On other grounds the system of capping the lens during exposure should be repudiated, the play of foliage in the wind being as much a part of nature as the immobility of the trunk."

**COLOURLESS VARNISH WITH COPAL.**—To prepare this varnish the copal must be picked; each piece is broken, and a drop of rosemary oil poured on it. Those pieces which, on contact with the oil, become soft, are the ones used. The pieces being selected, they are ground and passed through a sieve, being reduced to a fine powder. It is then placed in a glass, and a corresponding volume of rosemary oil poured over it; the mixture is then stirred for a few minutes until it is transformed into a thick liquor. It is then left to rest for two hours, when a few drops of rectified alcohol are added and intimately mixed. Repeat the operation until the varnish is of a sufficient consistency; leave to rest for a few days, and decant the clear. This varnish can be applied to wood and metals.—*Journ. Applied Chem.*

**INFLUENCE OF COLOURED LIGHT ON PLANTS.**—Recent experiments by L. Cailletet confirm those made many years ago by Morren, of France, with regard to the influence of the luminous rays in vegetable growth. The former advances a step further by including the red, as well as the yellow ray, among those most favourable in promoting the decomposition of carbonic acid gas by plants. All the rays more refrangible than the yellow are powerless in this respect. Under the influence of green light, not only does no decomposition take place, but new qualities of carbonic acid are formed, the exhalation of the gas by the fresh leaf being nearly as much under this condition as when placed in the dark. Light passed through a solution of iodine in bisulphide of carbon prevents decomposition of the acid, and, says the *New York Tribune*, the appropriation of carbon by the plant, but does not seem to increase the quantity of acid, which might be inferred from the fact that the violet is the most refrangible of the coloured rays. Many experiments have been made in this country which give the same general results of those of Morren and of Dr. Daubeny, of England, but differ somewhat from those of Cailletet.

## To Correspondents.

A. P. A.—The iodizing solution of the collodion you mention contains a bromide as well as an iodide. 2. The *Photographic News* is published every Friday morning at 9 o'clock, and the delay in obtaining it must be due to your agent, who ought to explain to you. 3. We believe the next collodion you mention contains a bromide, but we are not certain. 4. You may, for special purposes—such as preparing dry plates—add an extra proportion of bromide with advantage; bromide of cadmium, being most soluble, is most suitable to your purpose.

J. C. D.—The yellow sample of paper will probably answer pretty well for covering a background screen. You will best ascertain by pinning a piece to a background and photographing it. It may possibly turn out too light. We prefer blinds to skylights to run on rods fixed at ridge and eaves. We are glad to hear that you like Mr. Robinson's Art Lessons.

YOUNG.—You are in error in fancying that a picture could be obtained by any reasonable exposure on ordinary excited albuminized paper in the manner you describe. You fail simply because the light is insufficient and the surface not sufficiently sensitive for producing a picture. An enlarged image, obtained by the light of the north sky, is not nearly sufficiently brilliant to print on albuminized paper. You might possibly manage it on iodized paper and development; but then the exposure would be very protracted. There is no process more sensitive than the development printing process on bromo-iodized paper. You could produce an enlarged negative by the method you tried, and print from that on albuminized paper. 2. The solution for silvering brass to which you refer as sold in the street was probably a preparation of mercury. The red powder at the bottom was probably iodide of mercury.

- Such a method of "silvering" is useless for ordinary purposes.
3. Yes: it may be used for landscape either as a portrait lens, stopped down, or the front lens may be used alone, and, being of longer focus than the combination, it will cover a larger plate.
4. The landscape you enclose would have been better if the masses in the left-hand corner had been balanced by some object in the right.
- J. B. CARTLIDGE.—Acetate of morphine is a salt, generally in a white amorphous powder, and can be obtained of most chemists. Permanganate of potash is a salt, consisting of purple crystals. You can obtain either of most dealers; certainly of Mr. Thomas, Mr. Rouch, or other photographic chemists. The recipes to which you refer are valuable in rendering glass non-actinic; and the varnish you mention also answers well. We should think that it might be used to the glass of a lamp to make the light non-actinic.
- P.—The source of failure is in the mode of developing. Before adding the iron solution add to it a drop or two of nitrate of silver solution. You will find in our last Volume several articles in which, amongst the causes of failure discussed, this one is especially pointed out. Try again, and let us know the result.
- F. M. YOUNG.—Collodio-bromide of silver plates may be used in the wet state; but they must receive the tannin coating, and must be developed with pyrogallie acid, not iron; in fact, developed as Mr. Mawdsley directs in our last YEAR-BOOK for dry plates. 2. Dissolve the silver in the alcohol before making the collodion, and, when required, add the alcoholic solution of bromide; or add sufficient of a saturated solution of nitrate of silver in distilled water to plain collodion, and then add alcoholic solution of bromide. 3. The silver bath does not require modifying when sulphocyanide toning is used. The bath with either nitrate of soda or sugar may be used as well with the sulphocyanide and gold toning bath as any other toning bath. The bath is generally neutral; if not, it may be made so with chalk. 4. The time varies with the proportion of gold present: from five minutes to half an hour, according to depth required and other circumstances. 5. The negatives we intensified with permanganate were developed with protosulphate of iron and acetic acid solution. We have not tried it with a gelatino-iron developed negative, but in no instance did we fail to get the orange tint. Let us know your further results. 6. Coffee plates can be developed with iron, but not so well as with pyrogallie acid.
- H. S.—We are glad to learn the successful issue of your experiments. We shall be glad to see an example of the insoluble deposit.
- D. J. W.—We regret that we cannot give you any definite information as to the probability of your getting an engagement in a first-rate London studio for the purpose of getting an insight into the mode of working. As a rule, photographers in good practice do not care to employ assistants on such terms; but it is probable that you would best serve your purpose by inserting an intimation of your desire in our advertising columns. You can call upon us if you wish for more direct information.
- J. B.—You will find details of the Eburneum process in our YEAR-BOOK for 1866, stated by the originator, Mr. J. Burgess, of Norwich.
- R. L. M.—The old red insensitive collodion of which you speak cannot be made useful for producing negatives, especially as you remark that the film is perfectly rotten.
- HUGO.—The new chloride of silver voltaic battery of Messrs De la Rue and Muller is remarkable for the intensity of the current which may be obtained from it, but it would not compete with Grove's battery for the economical production of the electric light. Forty cells were used to exhibit its powers at the Chemical Society's Soiree. The novelty consists in the generation of a comparatively powerful electric current in a battery of which the cells are charged with a *single liquid*. Salt brine, which soon becomes partly converted into chloride of zinc, is employed as the exciting fluid. The new battery, elegantly mounted on a mahogany stand and in series of ten cells, can be procured from Mr. William Ladd, Beak Street, Regent Street. You do not state how the toning bath was made which has become inert, so that we cannot speak with certainty as to the remedy. Try adding a few drops of a fresh concentrated solution of chloride of gold to it.
- LOST IN LONDON.—We have used a sulphocyanide toning bath immediately it was mixed, and months afterwards, with success; but, on the whole, prefer it fresh mixed. Increasing the proportion of sulphocyanide reduces the tendency to a pink tint in the lights. The addition of a little chloride of sodium to the bath also decreases the tendency. We do not dislike the rosy tint of the print sent. 2. More front light would not have been an improvement.
- J. A. R.—You do not state the nature of the difficulty in getting good tones. Do the prints tone too rapidly and become too blue? If so, make the bath still more dilute. The hypo and gold bath is made by adding about 4 grains of chloride of gold (first dissolved) to a pint of fresh fixing solution. The coffee plates are stated to require ordinarily three or four times as much exposure as wet

plates; but it is quite possible that under some circumstances ten times would not be too much. We will make enquiry into the error with which we regret to learn you have been troubled.

W. J. A. G.—It is quite imperative that you use both eyes in looking through a stereoscope, as you cannot get the effect of binocular vision with one eye. A limited effect of solidity may be obtained by examining a good photograph with a lens; but the proper effect of relief and distance can only be obtained by using both eyes. The two halves of a stereoscopic slide are dissimilar views of the same subject, such as would be seen by the right and left eye respectively, and these must be combined in the stereoscope as they are in natural vision in order to produce the true binocular effect of relief and distance. It is a common error with persons who have not familiarised themselves with the use of the stereoscope to fancy they can see better by closing one eye. You cannot judge correctly of distance in nature by the use of one eye only, as you may easily prove. There is only one reason why a stereoscopic slide must be examined by both eyes, and that we have just stated; namely, that the two pictures, being views of the same thing from two different points of view, can only be seen as one picture by two eyes. Two views exactly identical would be useless. 2. A perfectly fixed and properly washed print will not be injured by using warm water to remove it from its mount. Hot water as final bath in washing prints is a good thing.

CONSTANT SUBSCRIBER.—The process would require too much space to describe here. You will find it described in our last YEAR-BOOK, in the article on "A Simple Method of Enlargement." We shall probably have something to say on the subject shortly.

REV. J. H. JOHNSON.—India-rubber solution may be used safely without fear of injuring the bath. It may be used as preliminary coating to the whole plate, or only to the edges, as you may choose.

G. R. FITT.—On examination of the precipitate, it appears to be acetate of silver with a little reduced metallic silver, and a slight trace of chloride of silver, cyanide of silver. The peculiar lustre is characteristic of acetate of silver.

R. B. (India).—The dirty yellow or brown mottled markings and spots are due to imperfect fixation. Either from weakness, impurity, or exhaustion of the hypo bath, or from imperfect immersion, the prints are not perfectly fixed, and insoluble hyposulphite of silver, being formed in the paper, decomposes in the washing water, causing the dirty brown mottling in question. The prints sticking together and not being kept in motion will cause a few prints in a batch to suffer when others are all right. The remedy is plenty of fresh strong hypo, and care to see that the prints get all thoroughly immersed and brought under the action of the fixing agent. Thanks for the print.

\* \* Owing to the unusual pressure on our space, many articles are compelled to stand over until our next.

Several Correspondents in our next.

### Photographs Registered.

### VITRIFIED INDIA-RUBBER SHEET.

ABOUT three months ago we called attention to a new material, which had been introduced in Paris by M. A. Marion under the above name, possessing valuable qualities for many photographic purposes. We have just received from Messrs. Marion and Co., of Soho Square, some sheets of the new material for experiment, and a brief description will doubtless interest our readers.

The "caoutchouc pellicle" is in sheets the size of photographic paper, about 22 by 18 inches. It is thin, colourless, transparent, exceedingly pliant, possesses a fine surface, and is waterproof, or nearly so, not being affected by fluids until after long treatment, and then only slightly. It is exceedingly tough, bearing considerable strain without tearing, and is slightly elastic, stretching a little when pulled.

The multiplicity of purposes to which a material having most of the properties of glass without its fragility, and which might be called flexible glass, may be applied in photography will occur to most readers. At present, however, but few of its special uses have been pointed out. M. Marion proposes it as a means of transferring negatives from glass, and forming a convenient support, free from risk of breakage, permitting the negative to be used with either side in contact with the sensitive paper, without loss of sharpness, and rendering the storage of the negative an easy thing. He treats the negative film with a suitable varnish, applies the transparent pellicle, and, when all is perfectly dry, immerses the plate in water, by which the collodion film is detached from the glass, and is removed, adhering to its new support. He also proposes it for use in carbon printing, as rendering unnecessary one of the transferring processes usually necessary. The sensitive pigmented gelatine, being applied to the new material, might be printed through it, and then developed without mounting previously. The print might be finally mounted with the vitrified sheet uppermost as a protection, or steps may be taken after mounting to remove it.

We foresee some slight difficulties in the application for carbon printing, which, however, may probably be overcome in practice. If the vitrified sheet be left in contact with the carbon image it will interfere somewhat with the artistic character of the result, as a glazed surface in the lights generally lacks the feeling of purity and repose which belongs to a matt surface in the lights of a paper picture. To secure the best surface, therefore, it would be necessary to remove the caoutchouc pellicle after the final mounting, and at present we are not sure that this could be done successfully. The material, however, is one of which carbon experimentalists will be glad to make trial. We hope shortly to be able to record some results in this direction.

At present we have only had opportunity for experiment in two directions with the sheets sent to us. We have employed it as a protective surface to small pictures, in a manner similar to that in which sheets of collodion and gelatine have been used, and also as a substitute for glass in taking negatives. For the first purpose its application is simple and easy. A sheet of the material, having been cut to the required size, is immersed for a few minutes in clean water, or dilute alcohol and water would be better still. The picture to be protected is then wetted, either by holding under a tap, or immersing in a dish of water. The wet, vitreous sheet is then brought into contact with the wet surface of the print, which till then is kept in a horizontal position: the two being then raised into a vertical position, and drained, the surfaces come into close contact, the water running out from between them driving away all air-bubbles. A sheet of paper is placed over the surface, and the whole rubbed well down to secure firm contact. The protected print is then dried under pressure. The appearance of the finished print is very similar to that of a print "enamelled" with gelatine and collodion.

In our attempts to use the vitrified sheet as a support in producing negatives, we proceeded as follows:—A piece of the sheet is cut about a quarter of an inch less than a plate of glass of any suitable size. The vitrified sheet is moistened at the back, and placed on the plate of glass, to which the moisture causes it readily to adhere. It is then coated with collodion, which, flowing over the edge of the sheet and up to the edge of the glass, protects it from displacement in the nitrate bath. This done, the manipulations are conducted in the usual way until the negative is finished, when it is easily removed from the glass by running a penknife round the edge and lifting away the negative on its limp transparent support. There are certain precautions necessary in these manipulations: it is important to see that the pellicle is quite flat on the glass without wrinkles, and that the edges do not curl up so as to permit the collodion to flow under between the vitrified sheet and the glass. The inconvenience and imperfection which would arise if care were not taken in this respect will be readily understood.

The most curious difficulty we met in using the new material as a substitute for glass in taking negatives is one which we hope is exceptional, or in any case we are disposed to believe it is avoidable. It is this: the exposure required is much longer. In our first experiments we were puzzled to find each negative considerably under-exposed, and concluded that the chemicals were out of order. In the course of further experiment, however, in using a piece of the vitrified sheet much smaller than the glass on which it was manipulated, we found that the excited film on the bare glass was over-exposed, whilst the same excited film where it rested on the new material was thin and under-exposed. This fact was verified by

further experiment. Its cause remains to be ascertained, and possibly removed. Another detail may be mentioned. After passing through the various manipulations, and being subjected to the action of the various solutions in taking a negative, the pellicle acquires a somewhat opalescent appearance in place of its former perfect transparency. This effect continues on spontaneous drying, but disappears on the application of heat.

We may here mention an ingenious application which Mr. Woodbury has for some time contemplated making of such a material as this. He proposes to sensitize a long strip of it by some trustworthy dry process; and, providing a camera with a couple of rollers, wind off from the supply roller sufficient for a negative. After exposure this would be wound on to the other roller, and a fresh supply at the same moment brought opposite the lens for further use. The compactness and convenience of such an arrangement will be readily understood. The working out of such an arrangement is a matter of detail which we need not discuss here.

The exact nature of the material and its mode of preparation are, of course, M. Marion's secret; but as photographers rarely like to work with materials of the constitution of which they know nothing, we may state at once that there is very little doubt that the basis of this fabric is collodion; and although it is named vitrified india-rubber, it is very doubtful whether india-rubber enters at all into its composition. The strong and peculiarly characteristic smell of castor oil is one of the first characteristics which came under our attention in examining the pellicle. On treating it with benzole it remains unaltered. It is at once penetrated by ether, and softened, but, like collodion films under such circumstances, not readily dissolved. It burns in the rapid explosive manner of pyroxyline, leaving a little sticky residue like burnt oil. Dr. Vogel described in our pages about year and a half ago the "leather collodion" of Herr Grune, made from plain collodion containing four per cent. of soluble cotton and three per cent. of castor oil, and this appears to be a substance of a similar constitution. Dr. Vogel proposed to supplement a film of the leather collodion with a layer of india-rubber in certain cases, and he describes the films so prepared as very solid and a little elastic. The object for which the preparation was then proposed was the transfer of negatives. It appears probable that to M. Marion has occurred the happy thought of expanding this idea, and forming a transparent fabric in sheets ready for use, which will have a variety of valuable applications. Whatever the precise nature of material employed, the skill with which it is prepared, and the beautifully transparent, tough, and flexible pellicle produced, confer a boon on photographers generally.

#### PHOTOGRAPHY AND THE ABYSSINIAN EXPEDITION.

We are in receipt of intelligence concerning the staff of photographers attached to our army in Abyssinia. From a private letter, which left that country on the 20th March last, and has been considerably delayed in transmission, we learn that Sergeant Harrold, Royal Engineers, the chief photographer, has been remarkably successful in the fulfilment of his very laborious and difficult duties. His labours commenced at Annesley Bay, where a large panoramic view, on three negatives, was taken of the pier, shipping, store-houses, &c. As soon as this had been completed, he was at once ordered up the country to Senafe, views of the mountain passes being obtained *en route*; and here he remained with his staff for a short time, taking extensive photographic sketches of the camp and environs. From Senafe he moved forward with the first brigade of the army, accompanying General Merewether on some of his exploring expeditions, and obtaining views of the country which considerably facilitated the construction of maps and plans required for the Quarter-Master General's Department. Sergeant Harrold

speaks in high terms of the equipment with which he was supplied, and especially of the packing thereof. In enumerating the many difficulties with which he has had to contend, and more especially with regard to the carriage of the apparatus, he says:—"Two of our mules had a regular dance round the camp one day, with a couple of our boxes dragging behind them. One of them rolled over on his back three times whilst carrying two of our plate-boxes, and afterwards fell down a place called the Devil's Staircase. I am surprised the equipment has stood so well as it has, and I think Mr. Meagher deserves great credit for the substantial manner in which he fitted it up, for it has been exposed to all weathers, merely covered with some tarpaulins."

As regards operating, Sergeant Harrold tells us he has been very much troubled with the dust blowing into the dark tent, and, inasmuch as the country is in some parts exceedingly dry, and no rain has fallen for three or four years, the amount of dust everywhere is very considerable. The water has been very good throughout, but at times it was remarkably scarce. The collodion he took out with him perfectly fulfilled his expectations. He says:—"I am surprised the collodion stands the test of the campaign so well; I must say that both Thomas's and Ronch's work first-class, and give me no trouble whatever."

All the stores and chemicals have been found to work well, and, with the exception of some of them running rather short, there is nothing whatever to complain about. It is the difficulty of transporting the apparatus and fragile paraphernalia over bad roads and paths of the rudest description which constitutes the chief obstacle to be overcome, not to mention the unpleasantness of being obliged to find one's way from one out-of-the-way place to another, unaccompanied by a guide, and unprovided with an escort. At no time, however, was it necessary to leave the dark tent and baths behind, and there was no occasion, therefore, to employ the dry plates with which Sergeant Harrold had provided himself in case of emergencies.

Besides the reproduction of landscape views, the chief photographer had likewise to exercise his functions pretty frequently in taking portraits. Groups of the different native chiefs surrounded by their suites, of the Prince of Tigre, of Kassai, and many other dusky warriors, had to be taken; and when, as in some instances, these gentlemen refused to be operated upon except under the shelter of a dark bell tent, the task of producing a picture with the sun shining full into the camera was by no means an easy one.

Other interesting subjects for the camera were not wanting, as shown in the following:—

"I have had an opportunity of obtaining a few photographs of an Abyssinian bible, which I believe is about four hundred years old; it is rather an odd-looking book, the leaves being of parchment of a dirty yellow colour. My copies, however, give a very good idea of the original, and show well the rude sort of paintings contained in the book. I copied two portions of the Gospel of St. Mark, and likewise a cross belonging to a convent at Goona Goona. I was left behind with four men to complete some prints and to copy these articles, and found myself, when I had done, eighteen miles from the main body, in an unknown district, without a guide. We went a considerable distance out of our way before we again fell in with our troops, and then found out that we had marched in the wrong direction and had arrived at the wrong camp."

Sergeant Harrold certainly appears to be the right man in the right place, as combining within himself the qualities of a skilful photographer and the power of readily accommodating himself to any circumstances.

#### PANORAMIC STEREOSCOPE.

We have had brought under our notice a new form of stereoscopic picture and stereoscope, projected by Mr. W. H. Warner and Mr. Robert Murray, which, for a large class

of subjects, possess decided advantages over the ordinary form familiar to the public. A common aim amongst photographers for years past has been to secure a larger horizontal angle in their pictures; panoramic lenses, panoramic cameras, and wide angle lenses of various kinds have been introduced to secure this result, and with various degrees of success. From the name given to the new form of instrument we are describing the reader will probably come to the conclusion that its aim is to render in the stereoscope the panoramic effects, or greatly extended horizontal angle, to which we have referred. Such is not the case, however; the aim is rather to present a view in which the vertical angle included is twice the horizontal angle. The pictures are laterally of the ordinary size, and include less than the ordinary angle horizontally, but twice the ordinary size and including much more than the usual angle in height.

The idea upon which the adoption of a new form is based is an assumption that the angle of natural vision horizontally is only one-half of the vertical angle. Without adopting this more than doubtful proposition, we may remark the very evident fact that there is a large class of subjects of which the pictorial interest is limited to a very small space laterally, but in which the whole effect is spoiled if a similar limit be applied to the height of the picture. In many views of church interiors, for instance, the interest is confined laterally to the narrow limits of the nave or a single aisle, whilst vertically it is desirable to take in everything, from the base of the columns to the roof. To secure this it is often necessary to use a lens of short focus, rendering the important objects in a diminutive scale, and including others not needed. In the new form of slide, noble columns and lofty arches, surmounted by the tracery of an ornamental groined roof, are seen in fine proportions; nothing cut off in the height which is necessary to the effect, nothing superfluous in the width not required in the subject. So of natural glens and gorges, or avenues of trees, in which height is a material element of the natural beauty of the scene. In the stereoscope subject the most uninteresting piece of foreground, which could pictorially be very well spared, is of great value in giving space and distance when viewed in the stereoscope, and hence it is often important to retain that which at first sight would be cut off as a matter of course. It will be seen, we think, that for many subjects the new form has a special fitness, and will give a new value to the stereoscopic rendering of many scenes.

Many of the subjects taken by Mr. Warner in the new size, for the new form of instrument, are very fine, and admirably illustrate the peculiar advantages to which we have referred. They are described as being printed by the "new argento-carbon process of the inventor, the whole of the sulphur being eliminated from the paper, and albumen and a pure carbon substituted in its place; thus they are really as permanent and indestructible as they can be made." Of the meaning and value of this description we can give no explanation, beyond stating that the prints resemble good gold-toned silver prints, and are stated to have acquired by some treatment immunity from fading. The stereoscope, which is made in different ornamental patterns, is, we understand, patented, and will be introduced to the public by Messrs. Murray and Heath.

#### PHOTOGRAPHIC PIRACY OF ENGRAVINGS.

Our readers will remember a recent case of conviction for infringement of copyright in which Mr. Beal, of St. Paul's Churchyard, was fined £130 for the sale of twenty-six photographs of copyright engravings, the penalty of £5 being exacted for each sale. At the hearing, Sir Robert Carden refused to state a case for a higher Court, believing the matter to be one beyond doubt or question, both as to the offence and the penalty. On Thursday, the 23rd ult., application was made at the Court of Queen's Bench before Mr. Justice Blackburn, Mr. Justice Mellor, and Mr. Justice

Lush, sitting in banco, for a rule directing the magistrate to state a case for the opinion of the Court on certain points raised. The case is reported in the *Daily Press* as follows:—

#### EX PARTE BEAL IN THE MATTER OF CERTAIN CONVICTIONS UNDER THE COPYRIGHT ACT.

This was an application in the matter of twenty-six convictions by Sir R. Carden, under the Copyright Act, for the sale of photographs of paintings, or engravings therefrom, without the consent of the owner. Twenty-four informations had been laid by Mr. Graves, under the Art Copyright Act, 25th and 26th Victoria, cap. 68, for unlawfully selling photographs of certain of his paintings or engravings without his consent as, for instance, "My First Sermon," "My Second Sermon," "Ordered upon Foreign Service," and so forth, the paintings or engravings being registered in those names, and described as "painting in oil," or as "engraving," by such names. At the hearing before Sir R. Carden various legal objections were taken, some of which were rather technical, as that the paintings were not sufficiently described in the registry, &c. The magistrate overruled these objections, and, as he considered them technical, refused to reserve them for the Court by stating a special case. One of the points was certainly substantial in the sense of the practical result. The penalty upon "each offence" being £10, and there being proof of sales of photographs upon two occasions—in each of which eight were sold—it was objected that there were only two "offences," but the magistrate convicted for sixteen offences, and imposed mitigated penalties amounting to £130.

Mr. G. Francis moved for a rule or order directing the magistrate to state a case for the opinion of the Court upon these points.

The Court, however, after a good deal of discussion, refused the application on the ground that none of the points were so far doubtful as to deserve consideration. As to the point of description, all that the Act required was a short description of the nature and subject of the work, and they thought that the description was sufficient. There could be no reasonable doubt as to what were the subjects of the pictures, which were well known. Then it was objected that the photograph was not a "copy" of the painting; but they thought that it was. Lastly, it was objected that each act of selling was only one offence, whatever the number of the copies sold. But the Court thought otherwise—that the penalties were cumulative, and that the selling of each copy was a distinct offence. It would have been a monstrous absurdity if a man might sell a thousand copies at one time, and only pay a single penalty. It would be well worth his while to do so, and such a construction would make the statute nugatory. The object of the Act was obviously to prevent the sale of copies, and therefore the sale of each copy was an offence within the Act. There was nothing, therefore, in any of the points raised to require a case to be stated, and therefore a rule would be refused.

#### ECHOES OF THE MONTH.

BY AN OLD PHOTOGRAPHER.

MR. McLACHLAN'S DISCOVERY—THE NEW INTENSIFYING PROCESS—PHOTOGRAPHY IN THE SENATE HOUSE—CONVALESCENT HOSPITAL FOR PHOTOGRAPHERS—PHOTOGRAPHIC CONVENTION—SEL CLEMENT—CABINET PORTRAITS—SOCIETIES.

MR. McLACHLAN has spoken; and I must confess that, in company, I fear, with many hundreds more, I feel sadly disappointed. The fulfilment does not seem worthy of the promise. I ask myself, what practical information have I gained which I did not possess before? And I am afraid I must answer, very little. I ask myself, what part of my usual negative operations shall I change in consequence of Mr. McLachlan's disclosure? And I fear I must answer, none. And as I had given some faith to Mr. McLachlan's announcement, I feel, as Jonah did when his gourd had been destroyed, that I do well to be angry. And yet I do not charge Mr. McLachlan with breach of faith, or humbug, or some other of the crimes which in pretty little epithets I have heard hurled at his head. I believe that he was perfectly honest in his conviction that he had something im-

portant to communicate, and, with an honourable and liberal mind, he was willing to communicate it to his brethren without fee or reward; nay, at a good deal of actual cost to himself, in waste of time and in travelling expenses, and at the risk, however valuable his communication, of meeting, at best, only misappreciation and ingratitude, possibly gibe and misrepresentation. Looking at all these facts, I feel satisfied that Mr. McLachlan is an honest and liberal-minded man.

But he has misconceived the facts of the case somewhat. I think that he has under-rated the knowledge and capacity of photographers generally, and that he has over-rated the novelty and value of his own mode of working. He has, I think, taken certain known facts of photography, and combined them into a system of working which, as a clever, practical man, he has found exceedingly successful, and that this system has assumed exaggerated proportions in his eyes. I am assuming, of course, that he has "made a clean breast" of his secret, and that no further novelty is yet to come in the promised paper. I must confess that I was a little bewildered by the *viva voce* statement of the case made by Mr. McLachlan at the Society's meeting. He should never have permitted himself to be tempted into a verbal account of the matter. His natural discursiveness runs away with him. I was very thankful to read your report, giving the simple facts of his statement stripped of the redundancy and freed from the digressions of his speech. I was glad to find, however, from your report, and that in the Society's journal, which contains substantially the same facts, that the impression I brought away was correct. I noticed, by the way, that these two are the only reports which have appeared; no attempt to render the speaker's remarks having been made elsewhere.

The gist of the whole matter seems to be, that Mr. McLachlan works with bath and collodion quite neutral, doubtless a wise thing to do where it is possible; which many skilful photographers have done and recommended from the early days of the collodion process, but which only very skilful and neat manipulators have been able to do with success. But I do not see how this is to free the collodion process from the thousand and one ills which it is heir to, or how it is to secure either certainty or permanency of general good conditions. The occult action of light, in giving a power to a neutral silver bath to hold oxide of silver in solution, and to reject iodide of silver, is curious, if true; but is it so? If Mr. McLachlan has still some important information to communicate not yet revealed,\* which will give us the promised results, I shall thankfully accept it, and will gladly withdraw any of my remarks which may do him the slightest injustice.

I have repeated the experiment you describe with permanganate of potash as an intensifier, and I am disposed at present to believe that it will prove the most valuable intensifying process we possess. As a rule, I prefer to obtain printing intensity with my iron solution before fixing; but as I am careful to avoid the slightest excess of density, it occasionally happens, with some samples of collodion which lose considerably in fixing, that the negative is then a little weak. The permanganate solution yields beautiful results, giving great brilliancy without any tendency to the coarseness so common when additional silver is piled on the image.

Photography has long been recognized as an art having wonderfully ramified forms of application; but I imagine that it will be long before it attains the kind of recognition in this country that it has secured amongst our transatlantic cousins. I see it stated that on one occasion during the great trial—the impeachment of the President—all concerned were observed to be arranging themselves with a view to effect for a memorial photographic group, which was to be taken as a souvenir of the occasion!

I have recently heard of a magnificent project which, if true—as I hope and believe it is—reflects great honour on the gentleman most concerned, Mr. Mayall. Everybody is familiar with the name of Mr. Mayall as one of the veterans of the art and a most accomplished photographer, and if the project to which I have referred be carried out, his name will be remembered by many generations of photographers. Mr. Mayall has, I am told, recently purchased an immense estate on the finest part of the Sussex coast, on which he intends to build a town. The medical profession, who have for a long time desired to build a convalescent hospital on that coast for members of their own body, but have not been able to obtain land, have made application to Mr. Mayall, who has offered to give them the necessary ground on condition that one wing of such hospital should be devoted to the use of photographers. Thus suffering members of our profession would be brought at once into contact with a fine atmosphere, the best advice, and cultivated companionship. Whether this will be carried out, or not, and how, remains to be determined; but I feel that photographers owe Mr. Mayall a debt of gratitude for the conception of such a magnificent idea.

I see from an American journal which has just reached me that a great convention of professional photographers has just been held in New York to resist the renewal of the bromide patent, to resist government taxation of photographers, and to adopt such united action as might be found beneficial to the interests of the profession. It is pleasant to see that in a country so extended as the United States anything like combined action could be secured in regard to such matters. The most amazing part of the business is, that such a patent as that for the use of bromides could ever have been enforced. A patent was obtained in this country for that purpose at the same time it was obtained in the United States, but no attempt has been made to enforce it here. The evidences of prior use, I presume, are too plentiful in this country.

I have recently seen some excellent prints produced by aid of the "Sel Clement," using a 60-grain bath. Assuming the analyses you recently gave to indicate the actual proportion of nitrate of silver present, this would be equivalent to a 30-grain silver bath. I think, however, that these prints are richer and more vigorous than a plain 30-grain bath would give, and point to the advantage of using nitrate magnesia or some similar substance in conjunction with the nitrate of silver employed.

The demand for cabinet portraits seems to progress very slowly in this country, whilst on the Continent, in all parts, I believe, they have already acquired a recognized and standard position. I have recently seen examples from Germany, Italy, and France, all so fine that I cannot help regretting that the universal adoption of this size lags so in this country.

The London Photographic Society's meeting was, as has been customary with it for some time past, a great success. Mr. Griggs read a capital paper, gave some most interesting demonstrations of the simplicity and value of photo-lithography, and distributed some beautiful examples of his work. Mr. McLachlan made the statement to which I have already referred, and promised to read a paper more fully giving his method at the next meeting. The North London had a conversational meeting. The South had a meeting of an exceedingly interesting kind, at once pleasant and instructive. Members having been invited to bring examples of photography with them, a large number of very charming pictures were exhibited, and formed subjects of conversation.

At the Liverpool Amateur Society Mr. Henderson read a very interesting paper on the use of Photography in Archaeology. At the Oldham Society Mr. Heaton read a capital practical paper on Photography in the Field, in which he paid a graceful tribute to the value of the art articles at present appearing in your pages, and for which I, in common with many of my friends, wish to express my

\* Our contributor will see from Mr. McLachlan's letter, in our present number, that he has further information to communicate. His present aim was to get solutions sunned, and then communicate further.—Ed.

thanks to Mr. Robinson. I shall personally be glad when he gets to the composition of figure subjects, which is a subject most interesting to photographers, as comprehending matters not within their control. The other societies have not presented many features of interest.

### PHOTOGRAPHY AT THE ROYAL CORNWALL POLYTECHNIC SOCIETY.

THE thirty-fifth annual report of the Royal Cornwall Polytechnic Society has just been issued. The consideration which photography has always received in its exhibitions gives its proceedings an especial interest to all connected with our art. In the section of the report devoted to the Fine Arts the following paragraph refers to the photographic contributions at the last exhibition:—

"The collection of photographs has certainly never been excelled, if it has ever been equalled, at any previous exhibition. Foremost among the exhibitors stands Mr. H. P. Robinson, of London, the beauty of whose works we have had to notice at previous exhibitions. One of his photographs, entitled 'Sleep,' represents two girls, evidently sisters, sleeping calmly and happily, side by side; and the air of peaceful repose and perfect unconsciousness which pervades their countenances is strikingly natural and truthful. Another very creditable production of Mr. Robinson's is a photograph from nature, entitled 'The Sisters.' The subjects are seated together in a chair, intently perusing a pictorial book, the arm of the elder sister being thrown lovingly over the neck of the younger. 'Ralph' is another excellent specimen of photography by the same artist, and equally well worthy of notice. Mr. Nelson K. Cherrill, of Tunbridge Wells, exhibited two portraits, entitled 'Emily,' and 'Idle Hours,' 'A View in Borrowdale,' 'An Old Oak,' and amongst his other productions were several views of the engine works of Mr. Penn, at Greenwich. Mr. T. M. Brownrigg, of Dublin, exhibited four excellent photographs of scenes in Ireland; Mr. William England, a number of pretty and well photographed Swiss views; and Mr. R. Griffiths, of Truro, Mr. Rowe, of Redruth, and Mr. Netterville Briggs, of Leamington, also exhibited several creditable photographs.

### ESTIMATING EXPOSURES.

BY ROBERT GILLO.

THE following method of estimating exposures, although not new, is, I believe, too frequently overlooked, and, I feel sure, will be of great service to any who may adopt the same plan.

Being in the habit of doing a great deal of landscape photography, using various lenses to suit the particular view, I have often, after taking a view with one lens, been bothered to know the right exposure for the same or a similar view with another lens. Trying to learn and remember the time of exposure for five or six lenses, each, perhaps, with four or five stops, is useless, and only confusing. I first accurately obtained the equivalent focus of each lens by drawing out the camera until I obtained a sharp image of an object the same size, measuring the distance from the object to the focussing-screen, and dividing the result by four. With a small pair of compasses I measured each stop, and found how many times it would go into the focal length. I have thus one lens 5 3-8 focus, stops 1-15, 1-21, 1-28, 1-36, 1-50 of the focal length; another  $7\frac{1}{4}$  focus, stops 1-25, 1-41, 1-60. The exposure necessary is, of course, as the squares of these numbers, near enough for practical purposes; one lens may be thicker than another, and so take a little longer; but this, when once ascertained, can be allowed for. I have a table of all my lenses clearly written and nailed up inside my van and tent. I find I am continually referring to it, and it saves an immense deal of calculation and guessing.

### ON NATURAL CLOUDS AND ATMOSPHERIC EFFECTS IN LANDSCAPE PHOTOGRAPHY.

BY NELSON K. CHERILL.

AT the close of my last paper upon this subject I stated that I intended writing two more articles: one to treat of the mechanical means by which clouds may be best secured on the same plate as the rest of the view; and a further one, to add a few remarks upon double printing. I have, however, upon consideration, determined to combine these two in one paper, fearing lest, by writing too much upon one subject, I may weary your readers instead of edifying them.

The first point, then, under consideration in this paper, is the mechanical arrangement for taking clouds and foreground on the same plate. The subject may be considered under two heads: first, and most important, the arrangement by which the exposure to the sky is rendered shorter than the exposure for nearer parts of the picture; and, second, the conditions of development to which it is also necessary to attend.

The most perfect apparatus for obtaining the first of these conditions is that of Mr. Johnson, as adapted by him in the pantoscopic camera; in this ingenious instrument, the hood placed in front of the lens contains a sort of diaphragm, in the form of a long slit from the top to the bottom, and this is so arranged that the opening of the diaphragm can be made larger at the bottom (wider, that is) than it is at the top; the light which comes from the landscape and the lens is thus, as it were, tapered off from the foreground to the sky, so that, as the camera revolves, the nearer parts of the picture receive an exposure longer than that of the sky, just in proportion as the diaphragm is wider at the bottom than it is at the top. This arrangement, however, necessitates the idea of a revolving camera. The same principle cannot be applied to the ordinary form of camera with its stationary lens. This is much to be regretted, as a motion so true and perfect, if it could be adopted, would be an inestimable boon to photographers generally.\*

Lenses are often fitted with flap shutters intended to be moved up and down during the time of exposure. This plan may or may not be good, according to the quality of the camera; on a strong, well-made instrument, that, when put up, is very firm and rigid, nothing can be better, as a rule, than the judicious use of a flap shutter. The mode of using it is as follows: when the shutter of the dark slide is drawn up, the flap is raised—by the finger and thumb applied to the milled-head—till it stands out at such an angle as will enable about the upper one-third of the plate to be exposed to the light; it should not be held still, however, in this position, but as soon as one or two oscillating movements have been given, a little more of the view—this time, of course, nearer the horizon—must be taken in, till, when all the foreground is almost done, the flap may be turned right up, and the sky taken in for the remainder of the time. This plan is very well in cases where, as I mentioned, the camera is quite rigid, but when there is the least tendency to vibration, or, even with a pretty strong camera, the least awkwardness on the part of the operator, a blurred picture is almost sure to be the result. I have therefore come to the conclusion that the flap or shade to arrest some of the superabundant sky light should be, as a rule, separate from the camera. When only a slight amount of shading is required, it can, I believe, be done better with the cap of the lens than with anything else; the cap being held between the forefinger and thumb, and made to dip down from above the lens, just so as to cut off the light from the sky; the cap should be moved from side to side, and also slightly up and down, giving, in fact, a circular motion. When, however, the shading needs to be of a very prolonged duration, I find it better to cut a rough outline of the view in dead-black paper, and hold this up in front of the lens

\* It could, however, of course, be managed by means of a circular front to revolve by clockwork, about six inches in front of the lens; but this would be very expensive, not to say clumsy.

to a similar end. This plan answers most perfectly; so much so, that I would advise any one who often required to make use of these shading dodges, to provide a stick to be stuck into the ground about six inches in front of the camera, and a little to one side, so as not to come into the view; the reason for such an arrangement being that, by its judicious use, the hand can be made to hold the paper shade with much greater steadiness and consequent good effect; or, when a very long exposure is needed, the paper might be fixed to the stick and there left. On one occasion I remember achieving a great success by means of two shades, one to protect the sky in the manner above mentioned, and the other applied to the lower half of the plate, to screen some breaking waves, while I wanted the plate to become impressed with the idea of a group of pine trees, about half a mile across the lake on an island. By means of the double screen I obtained the waves and clouds, and more detail in the trees than could have been obtained in any other way.

It must be borne in mind that there are two reasons for generally wishing to give a shorter exposure to the sky than to the nearer parts of the picture: one is, that the clouds *move*, and therefore would become blurred if left too long exposed on the plate; and the other, that there is often such a much greater body of light from the sky, so that the clouds become completely buried in the development under ordinary circumstances.

Now, whenever the clouds are in rapid motion, it becomes absolutely necessary to use a shade in the event of a prolonged exposure being needed; but when the clouds are comparatively still, as in calm weather is not unfrequently the case, the sole difficulty arises from the tendency to over-intensity, which often arises in the manner pointed out. In such a case, any means which will effectually lower the intensity of the developing action will be found most useful in securing cloud effects. The most effectual means for promoting this end\* are, I think, to be found in the suggestions contained in a paper communicated by me to the *News* of June 22nd, 1866. I think the best way to reduce the intensity of the developing action is to reduce the amount of free nitrate mixed with the developer. I have, in the paper referred to, suggested the use of iodide of potassium added to the developer as a means of reducing intensity; but I believe the same effect can be obtained, with a little more expenditure of time, by pouring over the plate, after exposure, a certain amount of water—say the same amount as would be used of developer. Let this well mix up with the silver solution on the surface of the plate, and then pour away (say) one half of it, and mix the developer with the other half; in this manner the ultimate effect of the developing solution in producing intensity will be very materially lessened; and in just that degree will the facility for taking clouds on the same plate with the foreground be, in many cases, increased.

In conclusion, a few words on double printing in its particular application to clouds. The plan which I have found most generally useful is as follows: The cloud negative should be "thin," and, at the same time, very transparent in its shadows. The sky of the landscape negative must, of course, print quite, or very nearly, white. When the print is finished so far, I put the sky negative into the frame, and the print behind it in its proper position; then, outside the glass of the frame, I hold up a screen of the same shape and form as the sky-line of the landscape. The whole is then exposed in the shade; but, during the exposure, the effect produced by the sky negative is modified, as occasion may require, by means of another shade, which is moved about all the time; by the combined use of the two shades—the one to protect the foreground, &c., from the light, and to make a soft edge to the sky-line; and the other, still more to soften down the lower parts of the sky, and otherwise generally to modify the effect—I have been able to produce

the best effects, and in the shortest time: about two or three minutes for each print.

I do not think it at all a good plan to adopt a regular "blocking out" system of double printing for cloud effects; I have tried it, but the result is by no means so satisfactory nor so easy as the plan now mentioned of using two screens. In some cases, of course, one only may be needed; but I have generally found two answer best—one in each hand.

When any moderately dark objects project much into the sky, they may commonly be disregarded in these shading operations, for the reason that, after the light has acted on the paper to almost its full extent, a slight further exposure will not produce any further darkening; thus, trees, the masts of ships, &c., may often, with no disadvantage, have the sky printed right through them without the least injury. For just the contrary reason, great care must be taken where any light portions of the picture cut into the sky line, for here a very slight darkening caused by clumsy double printing will often betray the photographer's secret, even if it does not mar the effect of his picture.

Besides these two methods of securing cloud effects in photographs, there is another plan which, though not strictly photographic, is still often adopted, and that, too, with considerable success, sometimes so much so as to deceive even practised eyes; I refer to the modes of painting skies on the negative, which may be accomplished in many different ways. For a most able paper on the subject, from one whose works are the best testimony to the genius of its author, I would refer to Mr. Bedford's article in the *Year-Book* for 1868, in which the whole subject is treated of in a concise yet comprehensive style.

There is, however, yet one modification of this painting on the negative which I have often tried with great success, and which I have never seen published before; it is very simple, however, being as follows:—Make up a little ball of wash-leather strained over a small roll of flannel; rub up a little Indian-ink, and dab the ball down in the middle of it; then put the ball down several times with a dabbing motion on other parts of the palette, so as to distribute and partly to dry the colour; when the proper consistency is gained—which can easily be seen by a little practice—work on the back of the negative with the ball, by this means taking up fresh colour as needed. In the course of a very short time the back of the negative can be covered over with a film of black paint, which will render the sky much lighter in the print than it would be otherwise; of course only negatives with a "thin" sky can be treated in this manner. When perfectly dry, the clouds can be "taken out" from this darkened sky, and, with a little skill, the effect can be made most natural and effective. A damp paint-brush will be found to produce a wonderful effect upon the thin coating of paint, and in a short time clouds may be made which, as they print *darker* than the general surface of the sky, may be made to serve many artistic purposes, which cannot be served under the usual modes of painting-up skies, as, by the usual plans, the clouds print lighter, rather than darker, than the general tint.

## PICTORIAL EFFECT IN PHOTOGRAPHY;

BEING LESSONS IN

COMPOSITION AND CHIAROSCURA FOR PHOTOGRAPHERS.

BY H. P. ROBINSON.

CHAPTER XIV.

"The axiom that the most perfect art is that in which the art is most concealed, is directed, I apprehend, against an ostentatious display of the means by which the end is accomplished, and does not imply that we are to be cheated into a belief of the artist having effected his purpose by a happy chance, or by such extraordinary gifts as have rendered study and pains unnecessary. On the contrary, we always appreciate, and therefore enjoy, a picture the more in proportion as we discover ourselves, or are shown by others, the why and the wherefore of its excellencies; and much of the pleasure it gives us depends on the intellectual employment it affords."—C. R. Leslie.

HAVING in the last chapter had a slight glimpse of the value of a knowledge of composition in arranging a figure,

\* That is, of course, after the usual well-known plan of using a stronger solution and quicker development has been found insufficient.

we now come to a consideration of pyramidal forms, a method of composition very suitable to single figures and groups.

It is, perhaps, as well to begin with a complete subject; therefore, as an example containing almost every element of formal artistic composition, and as a subject to which it will

be useful to return again and again for the illustration of various points to be commented upon, I this week select Wilkie's "Blind Fiddler" for my illustration. Well-known and familiar as it is to all, there is scarcely another picture in the whole range of art so useful to the teacher, or from which the student of the art of picture-making could learn

so much. This is not because of the subtilty or ingenuity of the arrangement, but quite the reverse. To those who have the slightest inkling of composition, the art displayed is very noticeable, defying the teaching of those who say "the greatest art is to conceal the art," and that all the artist has to do to produce a work of art is to take a bit of nature, no matter what, and imitate it faithfully.

There is no doubt that the maxim that the art should be concealed is good enough, but it is one of those rules that the student should use with judgment, or it will cripple him. It should be taken in the sense of a protest against academic formalism. Burnett says on this subject, "Concealing the art is one of its greatest beauties; and he best can accomplish that who can discover it under all its disguises. I ought, however, to caution the young artist, on this hand, not to be too fastidious in trying to conceal what can be obvious only to a small number; for in endeavouring to render his design more intricate, he may destroy character, simplicity, and breadth; qualities which affect and are appreciated by every one." And the quotation at the head of this chapter is much to the same purpose.

As regards composition, the pictures of Wilkie may be taken as safe guides by the student. Artists of every shade of opinion unite in regarding them in this one respect as perfect. Even Haydon, whose enthusiasm for grand art and contempt for subjects of a domestic character almost mounted to insanity, acknowledged that, as an artist, Wilkie will be a teacher and an example for ever. Speaking of this

great artist, in one of his lectures, he says, "His composition is perfection; there the youth may consider him infallible; it was the composition of Raffaele in a coarser style." And adds, "My not seeing the beauty of his works at first was entire ignorance; as my knowledge increased, my admiration went with it: exactly as I understood Raffaele, I understood the beauty of Wilkie's art."

The "Blind Fiddler," as far as the arrangement of its materials is concerned, would have been possible in photography; it is therefore a picture of which a long study and analysis will much benefit the photographer.

The composition consists of a series of pyramids built up on and combined with one another. The fiddler himself forms a pyramid, and being the motive of the picture, he is more isolated than any other figure, which gives him greater prominence, although he is not the chief mass of light; so that what Ruskin rather fantastically calls the "law of principality" is observed. But he is not left quite alone, but is connected with the principal group by the figure of his wife and child and the basket at his feet. This basket is made light, to strike the eye, partly to unite the two groups, but chiefly because it is the supporting point of the angle of which the old grandfather's head in the centre is the apex, and which is led up to by the boy in shadow warming his hands at the fire. The two little girls form a pyramid, and so do the mother and child, supported by the dog, which is again continued by the man snapping his fingers, again by the old man, who caps and perfects the whole group.

Notice particularly how the line of one side of the pyramid formed by the mother and child is carried on by the stick in the little girl's hand. All the figures are connected together in one grand pyramid by the dark and light spots formed by the cooking utensils over the fire-place; and the diagonal line is still further carried on by the slanting beam to the left, which again is balanced by the steps leading to the door. The perpendicular lines of the wall give stability to the composition, and the group of kitchen utensils and vegetables in the foreground, being darker than any other part, gives delicacy and distance, as well as scale, to the rest of the picture, and by contrast gives perfect balance to the group.

I have pointed out the leading lines only of this famous picture, sufficient to guide the student in his further analysis of its governing lines; but he will discover that there is not a line, however insignificant, that has not its equipoise and contrast; not two articles together but what have others added to form the group. A good example of this will be seen in the way the sieve and fryingpan on the wall are connected together and grouped by the gridiron and cup, which subordinate group is connected with others, and so on throughout the whole composition. I shall return to it again to help my explanation of other details of composition, such as repetition, harmony, and repose.

What could be more formal, regular, and artificial than this group, and yet what more entirely natural? If art—art regulated by laws—were antagonistic to nature, this would not have been the most popular picture of its year, 1806; nor would it have retained its popularity, and become, as it perhaps is, the best known picture ever painted in England.

#### CONVENTION OF PHOTOGRAPHERS IN THE UNITED STATES.

A "GREAT mass convention" of photographers has just been held in the United States for the purpose of considering and securing united action upon several subjects of vital interest to the profession. Primarily the Bromide Patent, under which American photographers have groaned for some time, demanded attention. This iniquitous patent having nearly expired, effort was about to be made, it seemed, by the proprietors to secure an extension, to prevent which was one of the objects of the convention.

The meeting was held in the Cooper Institute, New York, and was attended by about a hundred delegates. We condense an account of the proceedings from *Humphrey's Journal*.

After the nomination of officers, among whom were Mr. Bogardus, of New York, President; Black, of Boston; Whitney, of Glenn's Falls; Cramer, of Philadelphia, and a few others. Mr. Bogardus, on taking the chair, gave some good advice to the profession, pointing out how want of unity in action and petty jealousy injured the business, and suggesting that photographers should follow the example of many other professions, and unitedly promote the interest of the business, in place of running one another down by a ruinous competition, as is now the case in many localities. Many letters were read, all protesting against the Bromide Patent and excessive taxation. The President stated that the tax had been repealed since the convention had been called, but that as there might be danger of a new tax law being imposed by Congress it would be well to be wide awake.

Some facts were stated in regard to the first legal decision in favour of the Bromide Patent, which gave strong suspicion that it was a so-called *made-up* affair, and all agreed that the case had never been tried on its true merits. The particulars communicated made the strong suspicion almost a certainty, that the affair was a "swindle all round;" that some photographers had been deceived by their own lawyer and agents, who, after seeing Mr. Hubbard, advised them to pay up. It appears more pluck and resistance would have broken up the affair long ago. It was stated that Mr. McKenna, of Bedford, Me., who was condemned by a court there to pay a royalty to the present owner of the Patent (Mr. Hubbard), was on excellent terms with him; in fact they were staunch friends. On

the strength of this judgment other snits were threatened, and some frightened photographers paid; however, Mr. Wardwell, of Boston, Mass., resisted with pluck, and employed the well-known lawyer, S. B. Brooks, who forced Mr. Hubbard to withdraw his suit, and Mr. Hubbard paid expenses even to Mr. Brooks. Wardwell's counsel, to the amount, it was said, of \$800 dollars.

The following resolutions were then presented by a council appointed for the purpose:—

1. That the photographers are unanimous in resisting the extension of the Bromide Patent.
2. That the committee was authorised to use all ways and means to carry out said resolution.
3. That the old proverb, "In union there is strength," is applicable to this case.
4. That the isolation of individual photographers injures them all.
5. Proposed to organise a Photographic Union for the promotion of the interest of the art.
6. That this meeting shall organise permanently, charging the officers to mature plans for effecting a good national organization in the United States.

The first four resolutions were unanimously adopted, with little or no debate; the last two gave occasion to a spirited controversy about the probability of keeping such an organization alive; and after many members present had ventilated their opinions and made valuable suggestions, Mr. Gurney, of New York, proposed a subscription with the cash down, in order to have a small fund to start with; this was, after little controversy, carried with a large majority. An invitation of the Photographical Society to be present at their meeting the same night in the same building was received. When the day's proceedings terminated, the reporter of our contemporary remarks, "the subscriptions were coming in at a rapid rate, and greenbacks almost rained down on the treasurer from an eager crowd."

On the second day it was moved that to Mr. Gurney, Fredricks, and a few others (who had spent divers sums of money, ranging from \$200 to \$700, in order to have the stamp duty on photographs abolished, and successfully lobbied this through in Congress) should have their expenses returned. It was decided to have 3,500 pamphlets printed to distribute among photographers. The President stated that yesterday over \$400 had been subscribed, of which half had been paid cash down. Next it was proposed to adjourn to the 3rd of July in New York, as then a photographic exhibition is contemplated in this city; this elicited a proposal to reassemble the 20th of May in Chicago; another gentleman proposed Philadelphia. The result of this jealousy was that the meeting adjourned at 12 o'clock M., *sine die*.

#### Recent Patents.

##### PREPARING CANVAS FOR ENLARGEMENTS OR DIRECT PRINTING.

BY J. M. LOEWE.

DR. LOEWE is known to photographers as an ingenious and inventive man, who has projected many processes, of which none, unfortunately for him, have come into operation, from want of completion by the inventor. It will be noticed that the description of the following method, which obtained provisional protection only, contains no allusion to the kind of silver bath, or its mode of application, nor to the modes of developing recommended. The specification is as follows:—

I prepare linen, cotton, silk, and other similar material by giving it, firstly, a solution of 2 ounces of gelatine dissolved in 10 ounces of water; I then treat it in the manner hereinafter described with reference to the canvas. I take canvas prepared in the ordinary way for photographic purposes, that is, by using oxide of zinc or lead, and I avoid the use of iron instruments, and use, instead thereof, those formed of ivory or wood for spreading the coating upon the canvas; I then add 1½ ounces of virgin wax dissolved in essence of lavender to 1 pint of turpentine. The canvas is prepared with three coatings and dried spontaneously; and when dry, I dissolve 60 grains of iodide of zinc in 2 pints of distilled water, and, with half a potato and

very fine pounded pumicestone, rub this solution on the canvas, and dry it with a soft flannel till the surface becomes brilliant.

In carrying this invention into effect, I further use the following three solutions: the first for printing out or developing the object on canvas by sunlight; the second for enlarging by artificial light; and the third for printing by contact in a pressure frame:—

*First Solution.*—To the albumen of 100 eggs I add 10 pints of distilled water, 10 ounces of chloride of sodium, 5 ounces of chloride of ammonia, 60 grains tartaric acid, 1½ ounces carbonate of soda, 2 ounces iodide of potassium, 1 ounce iodide of ammonia, ½ ounce bromide of potassium, ¼ ounce bromide of ammonia, ⅓ ounce pure iodine, 20 grains nitric acid, 120 grains chloride of gold, 1 pint of sulphuric ether saturated with virgin wax, beaten together, and filtered in a funnel hermetically sealed. The solution remains five or six minutes on the material, which, when dry, is rubbed over with a soft flannel until a shining surface appears.

*Second Solution for Enlarging by Artificial Light.*—I use the same chemicals described in solution No. 1, in the same proportions, but add 3 ounces chloride of ammonia, 2 ounces of magnesium, 120 grains of pure iodine, 120 grains iodine of lithium, and 60 grains of iodine of cadmium.

*Third Solution for Printing in a Pressure-frame by Contact.*—To 2 parts of distilled water I add 1 part of solution No. 1, and add 150 grains of chloride of sodium, and 8 grains of gold to each pint.

## PANORAMIC APPARATUS FOR THE FIELD.

BY CAMILLE SILVY.

THE following specification describes M. Silvy's invention for taking panoramic pictures on sensitive paper.

My invention relates to a new and improved apparatus which, being combined with the camera-obscure now used in photographic apparatus, allows, by suppressing the ordinary frames and dispensing with dark tents, of taking panoramic views on all points of the horizon. This apparatus consists of a tube made of zinc or other metal, or any other convenient substance, in the centre of which is a movable little wooden roller, on which the sheet of paper made sensitive is wound. One of the ends of this sheet is stuck on to the roller, whilst the other end is fixed on another similar little roller placed out of the tube, and which serves to unwind the said sheet through a slot cut in the whole length of the tube. This tube, enclosing as aforesaid the sheet of paper, is then placed in another tube or socket fixed vertically on the left side of the camera-obscure, and, in order to operate, the sheet of paper is gradually unwound at the rear part of the camera-obscure, which is purposely of a circular form, by means of a second little roller which is put into another tube or socket fixed vertically on the right side of the camera. When a panoramic view has been taken, the paper is wound up anew in the first tube, answering the purpose of a sheath, and contains the latent picture, which may afterwards be developed by the ordinary means.

This description is supplemented by a detailed statement, with diagrams, after giving which, the specification proceeds:—

By the foregoing description the panorama of surrounding objects and places, and not of plane images, is taken by a special apparatus circular in form. The camera being furnished with its immovable frame, a lens so regulated as to avoid the necessity of finding the focus, the fresh cartridges are merely introduced and then taken away; the spare frames are done away with, as is also the dark tent, the papers made sensitive not requiring to be renewed, and the cartridges furnished with the papers made sensitive being at will substituted for one another as many times as there are different phenomenas to be taken.

Having thus described the nature of my invention, and the manner of carrying the same into effect, I would have it understood that I do not confine myself to the precise details above given, and illustrated in the accompanying drawings, as these may obviously be modified without departing from the principle of my invention; but what I claim and desire to secure by letters patent is, an apparatus assuming the shape of a tube, or any other form, in which is wound a sheet of paper made sensitive, and which may be developed and wound afresh in combination with a camera-obscure; the frame of which, or the

back, is circular in form, and the sides so arranged as to be able to receive the said apparatus, and allow the partial and circular development of the sheet of paper and its winding in order to take panoramic views on all points of the horizon, substantially as hereinbefore fully set forth and described.

## Correspondence.

### SEL CLEMENT.

SIR,—On my coming to London yesterday I was shown the number of your paper of the 27th of March, with the few lines it contains on the "Sel Clement." I cannot allow the sort of challenge you seem to suppose I have thrown at the analysts to remain as such.

In my article in the *Moniteur de la Photographie*, and in reply to the excellent Dr. Phipson, I simply stated that to my idea it would not be an easy task to find out the composition of the Sel Clement by means of the ordinary chemical analysis.

The gentleman of your staff who has analysed the Sel Clement concluded to its being absolutely deficient of any organic compound, by stating that no trace whatever of carbonic acid had been formed in the combustion tube. For me, substances containing carbon are not the only ones that are organic; but I consider as such all those which contain either hydrogen or nitrogen. At all events, the apparatus used by your friend was not properly arranged to show any trace of carbon, and it may have happened that the nitrous fumes formed during the combustion have reduced the nascent carbonic acid into carbonic oxide, they themselves being converted into nitric acid. However, I beg to state that some organic compounds—such as sugar, citric acid, &c.—when dissolved in certain reagents, do not exert the slightest reducing action on nitrate of silver, and that they begin to reduce it only under the influence of light, providing the solvent has disappeared, or has been somewhat modified. This, in all probability, explains many a phenomena: for instance, why the Sel Clement is not sensible to light alone; why the albuminized paper, sensitized, remains white; why it becomes yellow after a time, when some modification has taken place; why the simultaneous action of the albumen and chlorine of the paper and of light is required to effect the reduction necessary for printing; why, in the first moments of printing, the reduction is slow; and, finally, why, after a certain lapse of time, the reduction goes on at a quicker rate. Magnesia, no doubt, contributes effectually towards these results; although, to my belief, its influence has been greatly exaggerated in what has been said about it in the papers. Lastly, I have some very serious reasons, grounded on experiments, to believe that the organic compounds introduced, as stated above, in the preparation of the salt, are not removed from it by either evaporating or boiling.

But here I must stop. It is no business of mine to commit myself into indiscretions, or to enter into polemics. You yourself, Mr. Editor, will neither allow it or wish for it, especially when you are made aware that I know with positive certainty that a counterfeited Sel Clement is sold in London, and that on no small scale. The following is an analysis of the counterfeited product:—

Nitric acid	...	...	...	...	39 25
Metallic silver	...	...	...	...	25-20
Magnesia	...	...	...	...	9-10
Copper	...	...	...	...	traces
Lead	...	...	...	...	traces
Oxygen	...	...	...	...	1-85
Water	..	...	...	...	24-60

10,000

Is it to be wondered at that the Sel Clement should present irregularities? That the percentage of silver should vary? That the results obtained in the keeping, the printing, &c., should be contradictory? You will surely admit, with me, that I cannot possibly be made responsible for the evil effects of such counterfeited products as this one!

In consequence of these facts, I think—and I hope you will think with me—that some measures ought to be taken to safeguard the interest of the public and my own against dishonourable competition. Henceforth the 10-ounce bottles will have in relief, on the glass, these words:—"Sel Clement" and

"Preservative Nitrate of Silver." The corks will be sealed with my agents' trade-mark, a "Hammer and Pick," and the labels will be signed "R. Clement." In consequence, the consumers are requested to look carefully for, and to claim, those unmistakable signs of a genuine product.

Be so kind, sir, as to insert this letter in your paper; and accept my sincere thanks for your kind intervention in this occurrence. I only ask for my product to have a fair trial. If it should prove advantageous to photographic science, I have my reward; if not, none but myself suffers loss for my long and careful working and experiments to obtain this end. If it does what I say, and saves the employers much money, why should it not be used without disputing about its composition? With the new and explicit directions which will be now printed (I send you copy) I am confident of success.

The gentlemen (Messrs. Johnson, Matthey, and Co.) who have consented to take my agency for England, its colonies, America, and Germany, are doubtless known to you, and their name is guarantee that what is supplied from them is my genuine product, for the composition and success of which I am alone responsible.

It is necessary for me to say that the new bottles and labels are not yet made, and that stocks just now sold are not so distinguishable; but protection can be had by only buying direct at present from these gentlemen, or their business customers who have had it from them.

Accept, sir, the expression of my high consideration.

THE MAKER OF THE "SEL CLEMENT."

Paris, April 25th, 1868.

[We have received with this letter a number of exceedingly brilliant and rich proofs printed with the Sel Clement.—ED.]

#### MR. McLACHLAN'S DISCOVERY.

MY DEAR SIR,—Let me commence by thanking you for the tone of your leading articles. The neutral position you have confined yourself to might have been followed by your contemporaries with greater justice to me, at any rate, if not ultimately to themselves. You are well aware of the circumstance that caused me to give such a hasty outline of my process. Many others were equally well informed. I should have thought that the fact of my being stopped speaking because of the lateness of the hour would have prevented others going into detail for me. There was much that I wished to say, had time allowed, apart from the chemistry of the process, that must have struck any one with the least reflection. Upon my return to Manchester many of my friends waited upon me for further particulars. I explained to them many things which were not stated at the Society's meeting, and that would have been mentioned had time allowed. I only state some of them now as there is a probability of my being forestalled in another quarrel.

At present I consider my process as having been given in confidence to the photographic community, until I am allowed to read my paper. I would strongly advise all who mean to try my process, to further the sunning of their silver, and to add no potash. A small quantity of the silver, after sunning, may be taken from the bulk, to which add a drop or two of caustic potash (strength one grain to an ounce of distilled water), and then note the change. I think it is reasonable to suppose that if reflectors or lenses were arranged so as to throw as much light as possible upon shallow cells or dishes made so as to present as much surface as possible to the light, the preparation of the silver might be hastened. It also struck me to try the effect of Wilde's large electrical machine. Many other things I have mentioned to my friends, and asked them to take notes, for fear I should have my own ideas reproduced by others.

So far as any certain knowledge of the kind of change that has taken place in the silver, I cannot say; but my theory, I think, is quite as rational as any that has been advanced, and as I differ with all, the more credit to him who turns out to be right. My theory, of which further explanations in my paper, is the same I informed you of in London; viz., oxygen absorbed by the silver from the water, actinism and heat combined changing it to a kind of ozone. I have thought it might be possible to prepare a bath at once by the introduction of ozone. Different methods of preparing it might be tried. As it is rather mysterious in itself, it would have been better for Mr. Spiller, after having presented his report, had he

allowed me to make a full statement; for I am sorry to say he has misunderstood my written directions, a copy of which is in my possession. Indeed, he has not performed or properly described any of the experiments; and if the silver is prepared as he states, nothing but failure can ensue. In making this remark I have no option left me; if I had, I should have passed by Mr. Spiller's article, for I must either admit or disprove what Mr. Spiller has said.

I will now state what I know to be facts. Mr. Spiller wrote to me, March 2nd, to tell me that he had placed 700 grains of nitrate of silver dissolved in 5 ounces of water (ordinary nitrate). By return of post, in a letter dated March the 4th, I sent him written instructions as he desired; and it was only after my written instructions that he placed a second bottle of silver in the light according to my directions. I had never been informed that he had been making an experiment of his own by introducing chloride of sodium in the bath. Whether this is the cause of the change, or not, I will not undertake to say; but this is not my experiment. The silver, notwithstanding being tampered with, dissolved 20 or 30 drops of the potash solution, and remained perfectly clear. I was also told the bath was saturated with iodide of silver. Yet, upon adding many ounces of water to make to proper strength, it still kept perfectly clear. The great quantity of potash caused an alkaline reaction, and although in every way prepared contrary to instructions, clear pictures were obtained. Both bottles of silver were tested most carefully after sunning, and they were found to be perfectly neutral.

Coming to the bath, prepared so far according to my directions, and which had only been exposed something about half the time of the other, in condition (so far) as to allow my experiment to be fairly tested. This bath was spoiled through Mr. Spiller incautiously adding a great excess of potash. But he himself admitted to me that it dissolved a great portion of the oxide. These facts being witnessed by myself, I am bound to state them; and, taken in conjunction with his mistaken description of my process, I cannot come to any other conclusion than that he quite misunderstands every thing.

Mr. Editor, you take upon yourself to call my experiments empirical. Compare them with Mr. Spiller's; for did it never strike him or you that the same result might have been obtained without the addition of chlorine? I have no doubt it would have been if he had tried. If this is how chemistry decides, Heaven preserve me from having anything to do with it!

I should have stated, that before any experiments were tried by Mr. Spiller, I would not be bound by any of the results, as the silver was not of the proper kind, or the exposure long enough, considering the time of the year. This was not Mr. Spiller's fault, as I could not obtain for him at that time the proper silver. It was not likely I was going to run the risk of failure. Yet, for all this, the fact was fully proved that by exposing neutral silver to light, it would dissolve oxide of silver. I never meant any one to experiment at all, but simply to report upon certain alleged facts, and to give an opinion upon their value. Of course I did not object to experiments, but I knew the risk of failure through mistakes, such as actually occurred.

I again affirm that up to the present day we are in the same helpless condition. So far as any published information goes for our guidance, there have not even been proper directions given for the making of an iron developer, and there is positively no common-sense or reliable direction for preparing a silver bath. There is as great a lack of knowledge of the collodion. It has simply been a question of process with us. The great difficulty lies in ridding the bulk of photographers' minds of this fallacy. This is plain speaking, for I cannot afford to be a hypocrite in this matter, after having gone through the mill, as I have done, for my information. There is the right spirit in all the letters that have appeared in your journal.

After having read my paper, I will willingly answer all questions. My only object is the elucidation of truth. This can only be obtained by a diversity of opinion in friendly controversy, and if this is kept up I am sure the ultimate end of this discussion will advance our knowledge of the true principles of photography. I consider the London Society in honour bound to put my assertions to the test. This can easily be done by the organizing of a committee. This would put the whole affair in a nutshell; and if they should find out, like Mercurio, that I have not made a breach as deep as a well nor as wide as a church door, it is enough; it will kill a vile system of work-

ing that has daily sent hundreds home with minds distracted, and, no doubt, some to an early grave. Again I say, let us have trial by battle; so organize your committee.—I remain, yours truly,

LACHLAN McLACHLAN.

Stamp Office Buildings.

9, Cross Street, Manchester, April 28th, 1868.

#### MR. McLACHLAN'S DISCOVERY.

SIR,—I do not see how due credit can be given or justice done to Mr. McLachlan on account of the discoveries he has made and so generously given to the public, if, after inducing him to divulge his secret and getting his promise to read a paper at an early date, we try to anticipate him in any way. I think that all are in honour bound not to do anything until Mr. McLachlan has stated his own case, especially as, owing to the lateness of the hour, his verbal communication was cut short, and several matters omitted.

Since Mr. McLachlan's return to Manchester, and before any notice of an article to be forthcoming in the *British Journal*, I and several friends had an interview with him, in which he stated that the period of preparing the bath might be shortened by throwing a strong body of light by means of lens, condensers, or reflectors, through shallow glass cells or dishes made so as to present as large a surface as possible to its rays. He also stated that a bath might be prepared at once by the introduction of ozone, either electrically or any other way. Many other applications of his ideas were given by him, too numerous for this letter, but of which notes were taken.

I do hope photographers, as a body, will sympathise with the man who freely gives to them the fruits of his brain undeterred by the shallow-pate who, in every photographic circle, is so ready to get on his legs and say, either he had done the very same thing himself, or else had seen his grandmother do it.

Several gentlemen of standing in this city are aware of this letter, and, agreeing with its contents, would gladly have appended their names to it had time permitted me to wait upon them.—Yours truly,

J. E. WALKER.

Manchester, April 28th, 1868.

#### MR. McLACHLAN'S DISCOVERY.

SIR,—Whilst very unwilling to prejudice Mr. McLachlan, or come to a decision before his statement is completely made, there are one or two questions which I should like to add to those already asked in your columns.

If a collodion contains sulphuric acid, or something analogous to it, will not adding caustic potash produce sulphate of potash, or something analogous to it? Will not this produce in the bath sulphate of silver, or something analogous to it? And is not sulphate of silver a cause of pinholes?

Supposing Mr. McLachlan's statement of facts to be correct, how will it prevent the accumulation in the bath of ether and alcohol, and, from these, occasionally, fusel oil and other impurities, and also the changes by which aldehyde, formic acid, &c., arising from the oxydizing of the alcoholic accumulations in the bath?

Several other difficulties occur to me, but I will not now occupy your space with them. I do not ask these questions in a captious spirit, but with a sincere desire to have such difficulties resolved, if Mr. McLachlan can effect that desirable end.—Yours obediently,

F. C. S.

[The first series of questions may be answered in the affirmative. Sulphate of potash, being insoluble in alcohol, would be precipitated if formed in any appreciable quantity. We avoid the discussion of the question until Mr. McLachlan has made his full statement.—Ed.]

#### INSENSITIVE SPOTS IN MORPHINE PLATES.

DEAR SIR,—I have commenced this season with some experiments with morphine plates in which I have met with a difficulty which I do not find in any of the articles or correspondence in the *NEWS* relative to that process. It consists in sundry insensitive spots over the plate, varying in size from one-eighth of an inch down to a mere speck, shading off to the edges. I see when I wet the plate where these are about to develop themselves (not before), as they appear to resist the water for any length of time; and when it is poured off, then show themselves as dry spots. The bath and collodion produce excellent results used in the wet process. The morphine bath

I have renewed, and also filtered several times carefully, and have used both in a dipping and also a horizontal bath, the first of gutta-percha, the last of glass.

Can you point out the cause of these spots, and a remedy for them, as in other respects the process is satisfactory, and is much less trouble than the collodio-albumen, which I have also tried?

Your new intensifier and McLachlan's process are both matters which appear to me to be most interesting novelties.—I am, yours very sincerely,

F. LANE.

Rotherham, April 27th, 1868.

[Can any of our readers throw light on this difficulty? It is one we have not met with.—Ed.]

### Talk in the Studio.

CHLORIDE OF GOLD FOR SECRET WRITING.—During the late Fenian trials it transpired that chloride of gold was employed amongst members of the Fenian Brotherhood as a means of secret correspondence. A tube of the gold salt was found on the person of "Colonel" Burke when he was taken, and some crystals of sulphate of iron were found secreted in the toe of a stocking carried into the prison to Burke by a woman who brought him clean linen. Writing made with a solution of chloride of gold remains very faint and imperfectly visible until treated with a reducing agent like sulphate of iron, which at once darkens it and makes it clear and vigorous.

HYPO IN MOUNTING CARDS.—We have had several serious examples of the presence of hypo in mounting cards brought under our notice. We shall have something further to say on the subject shortly.

FIRE IN A STUDIO.—A fire occurred a few days ago in the studio of Messrs. Palmer, of Truro, which was happily extinguished before serious harm was done.

SOIREE OF THE MICROSCOPIC SOCIETY.—The annual *soirée* at King's College took place on Wednesday evening week, and was attended by upwards of 1,200 members and visitors. The exhibition of instruments, prepared objects, drawings, and photographs was very extensive and interesting, and altogether the display, as well as the attendance, exceeded any of the former notable entertainments of this excellent and rapidly increasing society. Amongst the photographs were beautiful specimens of the carbon process by Mr. Mayall, and of the process by Mr. Woodbury. The Rev. J. D. Reed obtained excellent illuminating effects by his new double hemispherical condenser, with flute-key adjustment of the diaphragm tongues for regulating the illuminating pencils. An exceedingly good result was obtained in Messrs. Murray and Heath's improved stereoscopic and pseudoscopic binocular microscope, in which an uninterrupted view of the object is secured in one body, the instrument being also usable as a unioocular arrangement. Some fine micro-photographs were exhibited by Mr. How, who in the course of the evening threw some interesting examples on the screen.

### To Correspondents.

J. ROBERTS.—To enlarge four times with the lens you name, the equivalent focus of which is, we believe, 8 inches, you would require a copying-box extending 60 inches: 10 inches between the object to be enlarged and the lens, and 40 inches between the lens and the sensitive surface. The rule in enlarging is, that the distance between the lens and the enlarged image should be as many times the focus of the lens used, and one time more, as the number of diameters the image is enlarged: thus, in enlarging four times with a lens of 8 inches equivalent focus, the distance is 4 times 8, and once 8 added, making 40 inches. The distance between the lens and object will vary between the length of the equivalent focus and double that focus: thus, for enlarging two times the distance between lens and object would be  $1\frac{1}{2}$  times the equivalent focus; for enlarging four times the distance would be  $1\frac{1}{4}$  times the focus. We repeated the table in question every year up to 1865, and then the demands on our space compelled us to exclude it. You can procure the *YEAR-BOOK* for 1865 still. 2. You can get black tones in the sulphocyanide toning bath by using a strong negative, printing deep enough, and toning long enough, but not too long. The strength of the sensitizing bath is not important, so long as it contains silver enough for the salting of the paper. A bath which will give good results with other toning baths will with this. The question of the additions you mention is not important. On the whole, an advantage is found in toning when they are present.

**EARNEST.**—In using a stereoscopic camera with one lens and Latimer Clark's sliding bars, the principle to be borne in mind is, that the camera must, in moving laterally, describe an arc of a circle of which the sitter or object to be taken is the centre; and the bars must be adjusted to different degrees of convergence for different distances, in accordance with this principle. When this is properly done, you will have no trouble in securing images which will combine. To assist in adjusting, mark the size of the picture, forming one-half of the slide when mounted, on the ground glass; focus the subject so as just to come within the lines when the camera is placed at one extremity; then move it to the other extremity, and if the adjustment be correct it will again just come within the space marked. It is the ratio of convergence rather than the length of the bars which regulates the proper position. Thanks.

**W. J. A. G.**—With the aid of a lens, using one eye, you obtain such an effect of relief as can be represented by light and shade; with the aid of the stereoscope on a properly produced slide, you get such an actual perception of relief as can be obtained by using two eyes, and so obtaining a view of two sides of an object; and the stereoscope is of no service in examining a picture which has not been taken from two distinct angles, such as those seen by the right and left eye. In using one eye, if the head were held perfectly still, no perfect conception of relief and distance could be formed; but nature is very beneficent, and readily provides compensations: by moving the head slightly, a view of all objects around, from two points similar to that seen with two eyes, is obtained. Where a person has not the good fortune to possess the use of both eyes, this means of compensation is unconsciously and valuably used; but the use of the stereoscope is one of the things, unfortunately, under such circumstances, quite lost. 2. The spot in the centre of the negative, under the circumstances you describe, is flare; its cause has been the subject of much discussion. It is believed by the best authorities to be an image of the stop, very much out of focus. It is chiefly found in portrait and similar combinations, and is most annoying where long exposures are necessary. Using a stop in front of the lens aids in getting rid of the spot, as also protecting the lens from the full light of the sky by shading it during exposure. 3. The photograph enclosed is very good indeed, and the tone excellent.

**G. C. C.**—The pink tone of the pictures forwarded is due to a general reduction of gold on the lights as well as the shadows. Sometimes, with a toning bath in good working order, if the prints be exposed to light during the process of toning, a similar result to that sent will be produced. It is probable that you have added some salt having a reducing tendency to the gold solution; but, of course, we cannot tell what. The colour of gold in subdivision depends on the size of the particles, and varies from a ruby tint to purple black. The size of the particles much depends on the mode in which the gold is thrown down.

**GLADIATOR.**—We can readily understand your explanation. The matter was too trivial and unimportant from the first to be worth half the attention it received. We corrected a blunder, and had no further interest in the attempts to ignore it. Your view of the matter was unquestionably sound. We hear from you too seldom.

**ELECTRO.**—Judging from the appearance of the print, we should think the cause of the want of richness in tone is due to the negative. With greater intensity in the negative, permitting deeper printing in the blacks without over-printing the lights, richer and deeper tones would be obtained. Probably a somewhat stronger printing bath would also help you. The lighting and general effect of the picture are good. It only lacks a little depth and richness. 2. Sulphocyanide of ammonium can be purchased of any photographic chemist or dealer. We do not remember its present price.

**OXONIENSIS.**—It is very difficult to say how long a commercial sample of collodion will keep good of which we do not know the exact constitution. It is probable that if you add from half a grain to a grain per ounce of bromide of cadmium to the quantity, and put it away in a dark, cool place, that it will keep.

**PERMANGANATE OF POTASH.**—Mr. Whitfield, of Scarborough, calls our attention, and that of enquirers respecting permanganate of potash, to his announcement in our advertising pages on March 27.

**D.**—Good ordinary water colours answer perfectly for tinting prints on albuminized paper. "Harmonious Colouring Applied to Photographs," published by Newman, Soho Square, gives full particulars.

**AMATEUR.**—There are various formulæ for preparing paper for enlargements. That employed by Mr. Solomon for enlarging by the magnesium light gives good results. It consists of 15 grains of iodide of potassium and 5 grains of bromide of ammonium to an ounce of water, and exciting on a 60-grain silver bath containing 10 minims of acetic acid in each ounce; develop with a saturated solution of gallic acid. You will find various articles on the subject in our back volumes. See, also, our YEAR-BOOK for 1865. If those particulars are insufficient, write again.

**COLLIDION.**—You leave us in the dark as to your exact manipulations in the morphine process. You remark that you follow implicitly the instructions in our YEAR-BOOK, and then refer to an iron developer without acid, which is not recommended there. It

is probably in this point that you err. The iron solution without silver has, we find, been a frequent source of failure. If you use the iron developer, add silver to it before applying it to the film. If you want a long keeping process, we do not recommend it. It is best suited to those who wish to prepare for a few days' work, not longer. As a rule, the conditions of long keeping involve the necessity of long exposure; and in that case we know of nothing better than the collodio-albumein, with a final wash of gallic acid. Mr. Gordon's modified gum process keeps well, and gives very fine results; but we have not had personal experience with it. We cannot tell the cause of the tardy development of your England's plates. The darkness of the subject was the probable cause. In our own experience, development has been completed in a quarter of an hour. Mr. England occasionally found, with difficult subjects and imperfect light, that the development was tardy, and in such case accelerated it by using alkaline pyro. 2. The deposit you describe was probably carbonate of silver, caused by the presence of a carbonate in the water. Your letter did not contain the crystal of which you speak. We are not very familiar with the collodion you mention, but have no doubt that it is good, and that, with the addition of bromide you propose, it will answer for dry plates. 3. It is generally due to the presence of some organic impurity in the nitrate bath.

**ARTHUR STRIDE.**—Avoid the washing in salt and water, and omit the addition of carbonate of soda to your solution of chloride of gold. This will give you a better chance of rich and deep tones. Use your fixing bath just twice the present strength. You are using it 1 part of hypo in 8 of water; it should be 1 part in 4 of water. Let us know the result.

**THE VIPER.**—The subscription to the London Photographic Society is one guinea per annum and one guinea entrance. To become a member you must be proposed for election by a member. As a member you will receive the Society's Journal monthly, as well as the general privileges of membership.

**THOMAS STOTHARD.**—We will make enquiry as to the formula for developing containing sulphate of zinc. Many photographers use the common crystals of nitrate of silver for every purpose, and find them answer well.

**J. H. (Stonehouse).**—We have frequently had similar spots brought under our attention. We cannot with certainty state their cause, but believe them to be the result of minute air-bubbles formed on the print whilst in the fixing bath, which cause spots of imperfect fixation where they occur.

**G. D. LYON.**—The causes of structural markings are known by collodion makers, who generally try to avoid the defect; but it often happens in this, as in many other things, that the best results are obtained when the conditions are nearest to, but just avoid, certain defects. In the case to which you refer you do not state sufficiently precisely the nature of the markings. They may be due to a glutinous condition of the collodion, which renders it difficult to get an even, fine film; or it may be due to moisture, causing crappiness in the film. Coating a plate in a damp atmosphere will often produce the latter defect, even with a good collodion. If you describe more precisely the nature of the defects we can give you fuller information.

**JOHN HAMPTON.**—We believe the card you enclose is toned in an acetate bath; but quite as much depends on the excellence of the negative as upon the mode of toning. 2. There is no very simple work on the subject. Various of the manuals contain much information; these, and our own pages, are the best guides we can recommend you.

**W. F. MORGAN.**—Thanks. The qualities of the pictures are very good indeed. Your application of the process is very successful.

**D. GRANT.**—A good half-plate lens will answer for taking the various sizes you require; but it will require a long room to produce card pictures with such a lens.

**EDWARD B. FENNESSY.**—Thanks. The idea is a good one, but it has been extensively carried out already.

**D. J. W.**—Respecting your wish expressed last week we can give you some information if you send us an addressed envelope.

**E. SPENCER.**—The colours you mention are good for all kinds of photographs. 2. There is no better mode of making oxygen for amateurs than the usual method with chlorate of potash and manganese. Other methods have been devised, but not readily applicable for amateur purposes.

**W. H. L.**—1. The peculiarity of the collodion becoming red and afterwards colourless is not uncommon, especially when methylated ether is used. It will not injure its working qualities. 2. Pure white wax may be used with advantage. By great care in using ordinary bees'-wax, staining the mount may be avoided. We frequently apply it without such stains occurring.

**N.**—We are unable to give you the information.

**DINSDALE AND Co.** in our next.

Several Correspondents in our next.

Owing to the extreme pressure on our pages, several articles, including Mr. Bovey's continuation of the subject of Silver Printing, "Copyright and Piracy," "Economical Use of Artificial Light," "Collodio-Chloride Process," "Modified Transferring Process," Literary Notices, and many other articles, are compelled to stand over until our next.

## CAMERA PRINTING AND COLLODION PRINTS.

SINCE the publication in our last volume of a description of a simple means of producing very fine enlarged prints in the ordinary camera, using a collodion film to receive the image, and transferring the film subsequently to paper, we have received many communications on the subject, chiefly from correspondents who wanted help. The two sources of difficulty have been the toning and transferring, upon which we shall offer a few further hints.

Before doing so, one or two further words of explanation as to the origin of this mode of working may be desirable. The method of producing prints on collodion in the camera, and afterwards transferring them to paper, was introduced many years ago by Dr. Moitessier, but did not come into very general use. Some time ago M. Disderi adopted this system of printing, and introduced it into this country a couple of years since as the *email* process, the great beauty and delicacy of the prints generally winning admiration. Up to recently it has been chiefly employed as a means of producing prints the same size as the negative, or rather smaller, the process being regarded as a substitute for albuminized paper printing in the ordinary manner. Until last year no practical attempt seems to have been made to introduce this process as a means of producing large prints from small negatives. Half-a-dozen years ago we produced some such enlargements, and transferred them to paper; but we could not, at the time, work the method fully out, and, leaving it for a more convenient season, overlooked it altogether. Last year it was simultaneously and successfully worked out, without any concert, and unknown to each other, by several able photographers, and the general details, as derived from several of them and from our own practice, described in these pages.

We have repeated these particulars because we have found that an impression prevailed in some quarters that the process was patented, in others that important details were preserved as secrets; and we have heard that a description of the process described as a secret has been vended in the country at the price of a certain number of guineas. We wish our readers to understand that no restriction of any kind exists as to the practice of the process. As to whether other modes of effecting some of the operations than those we have described exist, we of course cannot say; but we know that the method of working we have described is, if properly carried out, efficient and simple, and is identical with the modes employed by many able men. It should, however, be borne in mind, that in this, as in every distinct branch of photography, skill can only come from practice. Experience brings familiarity with minutiae, and success gradually seems to come naturally where failure used to result from the same operation, without the operator being

able to say upon what essential point present success or past failure depended.

The troubles as to the modes of toning are somewhat difficult to meet in any general statement, inasmuch as tastes differ considerably as to the best colour. The tone of M. Disderi's published prints by this process, which are amongst the most successful examples of it, is generally black. It is produced by first whitening with bichloride of mercury, and then, after washing, applying an extremely dilute solution of hyposulphite of soda. The chief defect attending this method consists in a tendency to coldness and greyness. The best means of avoiding this consists in securing a tolerably vigorous image at the outset, as it is difficult to obtain a deep black if the original deposit is thin and weak. A still warmer black may be obtained by supplementing the bichloride of mercury with a weak solution of sulphide of ammonia. We have seen some exceedingly rich sepia tones which were obtained by following the mercury treatment with ammonia-nitrate of silver. The richest black tones we have seen are those obtained by Mr. Burgess, of Norwich, in his Eburneum process, in which a neutral gold solution is employed. The bichloride of palladium, as we have before explained, also gives a pure neutral black. It should also be remembered that warm tints are most easily obtained in the toned and finished picture when the original deposit is warm in colour; hence the substitution of pyrogallie acid with acetic acid in place of the ordinary iron development.

The greatest difficulties appear to have been felt in the transferring process, many examples of excellent enlargement and fine toning having been sent to us spoiled only by failure in the transferring process. It is worthy of note that in almost every instance the failure has occurred where the print has been suffered to dry before removal from the glass, and the collodion employed has generally been of a kind unsuitable for transfer. There are three or four conditions imperatively necessary to uniform success.

The collodion should be of good body, and yield a tough film. A sample yielding a thin, powdery, adherent film perils the success of the operation.

An acid nitrate bath facilitates the film leaving the glass.

After toning, if the plate be immersed for a short time in a 20-grain solution of citric acid, or a dilute solution of acetic acid, the operation of transferring is materially facilitated.

The addition to each ounce of the collodion of a grain of white wax facilitates leaving the glass.

The application to the glass of a solution of bees'-wax in ether, which on being wiped off with a clean cloth will leave an almost imperceptible film on the surface, the presence of which will aid the film in leaving the glass.

The safest mode of proceeding is as follows:—After the picture has been toned and submitted for a few minutes

to the acid solution, and then rinsed, it is placed on a levelling-stand and covered with water. The paper to which the print has been transferred—which may be plain paper which has been coated with gelatine, and dried, or aluminized paper, or the enamelled paper sold for the purpose—having been cut about one-eighth of an inch less than the plate, and wetted, is placed upon the film; the top edge of the film and one side are then turned over the paper, the corner of the turned-over edges is raised, and, if the operations have been rightly performed, the whole will readily leave the glass; the water between the paper and film, draining out, will drive out air-bubbles, and the two surfaces will adhere perfectly. The print is then hung up to dry. Before perfect dessication has taken place the prints should be placed under pressure. This mode of transferring will, after a little practice, be found to present little difficulty, and will give a good result.

Soon after the publication of our last article on the subject, we received a note from Mr. Window, in which he says:—

"I have long used the collodion transfer process you lately speak of in the NEWS, for locket work and highly-finished larger pictures. The former are rolled on a polished plate to improve the surface; the latter I roll, while still slightly damp, on a piece of rough Saxe, to give a rougher surface. The effects to be got in colour on these are extremely good, and I believe they may be considered permanent. I tone with sulphur before transfer, and I have never found the least sign of deterioration."

The mode of giving a texture to large prints here indicated is, we think, worth attention as a means of securing some good effects.

#### TEST FOR BROMIDES.

THE difficulty of recognizing the presence of excess of other halogens is well known to experimentalists in this direction. In our last volume Dr. Phipson described an elegant test for iodine and bromine in the presence of chlorine. Mr. J. H. Hill, a surgeon of the U. S. army, describes, in the *American Journal of Science*, a ready and sensitive test for the presence of bromine in the presence of chlorine. It was found impossible, he says, to obtain by the ordinary methods of the books a certain and easy recognition of bromine when chlorine was present.

The Fresenius test solution of auric chloride produces, in faintly acid solutions of alkaline bromides, a colouration ranging from dark orange red to light straw colour, according to the strength of the solution. Iodides must be out of the way. Chlorides, however, do not interfere in the least. The following is the best way of applying the test:—Separate iodides by palladium, and after getting rid of excess of palladium by sulphuretted hydrogen, concentrate the solution to about 25 cubic centimetres. Select two test-tubes, of the same size and shape and colour of glass. Into one pour the solution suspected to contain bromide; into the other pour pure water, adding, perhaps, a trace of chloride potassium; add now to each test-tube a drop of chlorhydric acid, and then to each one drop of auric chloride solution. On now comparing the two tubes, particularly in the direction of their long axes, a yellow colour will be observed in the tube containing the bromide, and made very manifest by comparison with the other tube.

The following experiment shows the delicacy of the test applied as above:—One centigramme of potassic bromide was dissolved in one thousand cubic centimetres of water. Thirty centimetres of this solution, compared with thirty centimetres of a very weak solution of potassic chloride, gave a decided yellow colour. This experiment was varied by dissolving a gramme of potassic chloride in two thousand cubic centimetres of water, halving, and adding one centigramme of potassic bromide to the one half. Thirty centimetres of each of the two solutions now tested gave ample evidence of the presence of bromide.

The mixed chloride and bromide should be brought to the state of salts of the alkalis, if necessary, by precipitating with argentic nitrate, thoroughly washing, and fusing with potassic carbonate. If sodic carbonate is used, the subsequent reaction with the gold test is not so decided.

A test for chloride in the presence of bromide as simple and delicate as the above is much needed. The writer has sought long for it, but in vain.

#### PHOTOGRAPHIC PIRACY.

THE subject of photographic piracy has been frequently and prominently brought under the attention of various legal tribunals lately, and always with damage to the pirates. The recent case, *GRAVES v. ASHFORD*, in which fines amounting to £250 were inflicted, was brought before a higher Court to compel the magistrate to state a case. A rule was here obtained to have a case stated on a somewhat curious point raised. We append a brief report of the application, extracted from the *Times*:—

##### GRAVES v. ASHFORD.

This case raised an important question under the Art Copyright Act (Lord Westbury's Act) of 25th and 26th Victoria, cap. 68. There were fifty summonses taken out by Mr. Graves, the well-known publisher, against the defendant, for alleged infringement of copyrights in photographs. In one set of cases the complaint related to a photograph of the print called the "Railway Station;" the Act protected the negatives of photographs, and the photograph here was registered by the photographer, who took it from the print and transferred it to Mr. Graves. In this case it did not appear that he was proprietor of the copyright in the engraving (although there is no doubt he is proprietor of the engraving), as it was not proved to be registered, nor need it be so to be protected, as an earlier statute protects it without registration, only the penalty under that Act is only 5s., whereas under the late Act it is £10, a very serious difference. In another similar case, that of the "Second Sermon," it did appear that Mr. Graves was the proprietor of the original engraving. In both cases the photograph was not from one of Mr. Graves's photographs, but from the engraving. There were other cases as to the pictures entitled "The Morning before the Battle" and "The Evening after the Battle." The whole fifty photographs were ordered and delivered at the same time. The magistrate (Sir R. Carden) had convicted in all the cases, and refused to state a case for this Court.

Mr. Poland moved for a rule to compel the magistrate to state a case. His main point was that the photograph was not a copy of a photograph, but of the engraving, and that therefore the proceedings ought to have been under the earlier Act, under which the penalty was not so heavy. He also mooted the two points taken the other day in a similar case we reported—that the registration by the popular name of the picture was not sufficient, and that there could only be one conviction or one penalty.

The Court, however, negatived the two latter points, adhering to their former decision thereon; but they granted a rule to have a case stated on the first point, deeming it worth consideration.

Messrs. Graves and Son are not confining their raid against the pirates to London, but are pursuing evil-doers in the country. A week or two ago, at the Birmingham Petty Session, James Sunderland was summoned for having sold three copies of each of their engravings "Morning before the Battle," "Evening after the Battle," and "The Railway Station." A clerk had been sent down to Birmingham by Messrs. Graves and Son expressly to detect the issue of piracies of which they had received information. The defendant, in conversation with the clerk, told him that they were obliged to be very careful in selling copies of copyright, because of the risk. Defendant, who was represented by Mr. Ansell, pleaded guilty, and asked for time to pay the fines, having offered to give information as to the producers of the pirated copies. Another charge was made against the same defendant, of having sold a copy of "Taming the Shrew," with the name of Messrs. Graves and Son appended, such work not having been issued by them. A fine of £4 in each of the cases was inflicted, and 18s. costs, with the alternative of seven days' imprisonment for each offence in default of payment.

On the same day a charge was made against Mrs. E. A. Hulme for selling twenty-three pirated copies of engravings.

It was shown in evidence that in this case the transaction was between Mr. Brittain, a traveller for Mrs. Hulme, and the purchaser, and that Brittain received the money on his own account. The magistrate expressed his conviction that there was collusion between Brittain and the defendant, and inflicted a fine of £5 in each case, amounting to £115, or a week's imprisonment for each offence. Fourteen days were allowed for payment, on security being given.

### PHOTOGRAPHIC REPRODUCTION OF OLD ENGRAVINGS.

In a recent reference to the swift justice which has overtaken photographic piracies of copyright engravings, the *Athenæum* has some good remarks on a neglected field, which is legitimately open to photographers, which might, if properly worked, yield a good return to those engaged in reproduction. The remarks run as follows:—

"Loud have been the complaints and sharp the punishments with regard to pirates of artistic copyright in recent pictures, and the knaves who avail themselves of the property of others with consummate assurance reply that they are encouraging art in the process of their trade. There is one application of this defence which has truth in it. It is, that the dissemination of good and cheap photographs of fine paintings or engravings must benefit art. Has it never occurred to those who offend the law that by producing transcripts of engravings of great reputation and high prices, with expired copyrights, they might serve the arts and fill their own pockets honestly and without risk? Take, for instance, some of the fine prints of Raphael Morghen after Da Vinci and Raphael, 'The Last Supper,' the 'Circles' of the Vatican, 'Mater Pulehræ Delectionis,' 'The Transfiguration,' the 'Aurora' of Guido, the many plates of Velate, and Desnoyers' 'St. Catherine,' 'The Virgins of the Cradle'—'The Fish'—'The Veil'—'The Casa d'Alba'—'The Rocks'—and 'A la Chaise,' or Forster's 'Binde Altoviti'—called Raphael. The prints of Anderloni, Strange, Woollett, Longhi, &c., are, for the most part, unprotected and popular, and, so far as art value may be said to support the defence, superior to what is too commonly pirated. For example, we presume R. Morghen's print after Da Vinci's 'Last Supper' is no longer protected by copyright. The artist died thirty-five years ago, and the plate was engraved more than seventy-five years ago; yet there is not to be had a good and moderately-priced engraving by any hand of this the most famous picture in the world, the demand for copies of which is so great that almost anything sells—electrotypes and casts in low relief, tawdry-coloured German lithographs, vile etchings—at prices which would remunerate the photographer."

One difficulty which stood in the way of the conscientious photographer has been the uncertainty, in many cases, as to the existence of a copyright in engravings which they might desire to copy. In the case of very old engravings, many of which are most valuable, no doubt need be entertained. Where a question exists it may generally be set at rest by reference to the publication line. The Act 8th George 2nd cap. 13 enacts, in relation to engravings, that the name of the proprietor shall be printed on each copy issued, with the date of the first publication; and the copyright continues good for twenty-eight years from that date.

### Critical Notices.

THE MODERN PRACTICE OF PHOTOGRAPHY. By R. W. THOMAS, F.C.S. (London: Harrison, Pall Mall.)

This is a new edition of Mr. Thomas's excellent manual, of which we had occasion to speak on its first appearance in a complete form in terms of commendation. A number of valuable practical papers on the various operations of producing a negative had been issued in various ways by the author, and these, when collected together, were found to constitute a very capital guide to practice, and to need little beyond some introductory pages to give them the order and consecutiveness of

a complete treatise. An early demand for a second edition having been made, it appears, with some additional matter, the chief portion of which consists in a chapter on the permanency of silver prints, which will be read with much interest. Some of the views propounded are open, we think, to debate, and we shall probably, on a subsequent occasion, have a few observations to make thereon. In the meantime we can heartily commend a work which is distinguished by a concise, clear, and practical style from one whose name has for many years been held as a high authority in collodion photography. The work is admirably got up, and has the very useful and sensible addition of some ruled blank pages, for the insertion of new recipes and memoranda, which give so much value to works of reference.

ABRIDGMENTS OF SPECIFICATIONS RELATING TO PHOTOGRAPHY. Part II. 1860-1865. (London: Office of the Commissioners of Patents for Inventions.)

The valuable volume before us is a continuation of a project commenced by Mr. B. Woodcroft some years ago, in which he has conferred a most inestimable boon upon inventors and upon all interested in the progress of the industrial arts. The abridgments of specifications give the salient features of every invention for the protection of which by patent application has been made. The volumes are classified, that before us containing everything relating to photography a specification of which has been lodged at the Patent Office. The first part included all inventions specified under the new patent law up to 1860, and the present comprehends all from that time up to the end of 1865. No pains has been spared to make this a complete book of reference, and to give it historic value as a record of the progress of the art, so far as the patent records are concerned. A brief historical introduction gives some of the leading facts in the history of the arts, not connected with patents, commencing where Part I. left off, and continuing up to the year 1865, is also given. The indexes are excellent, giving in one table the names of the inventors, and in another the subject matter of the specifications; the latter is made more valuable by the new chemical nomenclature being appended to substances as well as the old and familiar names. This is a little book which should be in the library of all experimental photographers.

THE ART OF PHOTOGRAPHIC COLOURING, in Easy Progressive Lessons. By DAVID REES. (London: Published by the Author, Broadway.)

The author of the little manual before us appears to hold, with Dr. Johnson, that a great book is a great evil, and presents his lessons in the concise possible style, describing the various operations in consecutive order with great terseness and simplicity. A very valuable feature in the work consists in two cleverly coloured card pictures illustrating the mode of working described. The specimens of colouring will be found valuable, and worth to many more than the price of the book.

LOCAL SKETCHES ILLUSTRATED BY PHOTOGRAPHS. By W. H. WARNER.

MR. WARNER has here hit on a happy notion of issuing photographically illustrated sketches of interesting scenes or places. Each consists of a quarto sheet of stout tinted paper, folded in a large envelope. The sheet contains a brief sketch of the place selected, giving the salient points of interest, and a photograph, consisting of a half a stereoslide, of some important aspect of the place. The examples before us—Tintern Abbey, and Ross and its Neighbourhood—are good illustrations of this kind of work. Each contains such descriptive text as we have described, well printed in red and black ink; a ground-plan, in one case, of the Abbey, and in the other of Goodrich Castle, with one photo-

graph. The whole sells for sixpence, and will, we should think, find numerous buyers amongst visitors to any scene of interest or celebrity. In a commercial sense the idea seems to be an essentially good one, as it will afford a mode of using up odd halves of stereo-slides, and will often serve as a mode of advertising the stock of local illustrations which the photographer may have published.

## ON THE OCCURRENCE OF HYPOSULPHITES IN MOUNTING CARDS.

BY JOHN SPILLER, F.C.S.

I HAVE lately been making a somewhat extended examination of the various qualities of cardboard commonly employed for mounting photographs, and freely endorse the remarks made in your leader of the 10th April, upon the importance of instituting such enquiries with a view to pressing upon the notice of manufacturers the necessity of abstaining from the use of hyposulphite of soda as "antichlore." My experimental results prove that with some kinds of white cardboard the photographer's efforts in the direction of thorough washing will be completely set at naught by the large amount of hyposulphites contained in the card and returned to the print in the course of mounting.

The test for the presence of hyposulphite is at once so simple that every photographer has the means of ascertaining for himself the degree of reliance to be placed in the employment of the cards he may have in stock. I prefer for this purpose using the iodide of starch test, which is further useful in indicating the point at which the prints themselves are thoroughly washed. Prepare, in the first instance, a clear aqueous solution of starch, by rubbing 20 grains of arrowroot into a smooth paste with 1 drachm, or less, of cold water; then pour upon it about a pint of boiling distilled water, with constant stirring. Allow the whole to settle for twenty-four hours, by which time the broken starch cells and insoluble matter will have completely subsided. Now dissolve a grain of iodine in three times that weight of iodide of potassium with the help of a little water, and dilute it first with water and then with the clear starch water previously made. The solution will present a deep indigo-blue colour, which becomes bleached immediately by contact with a soluble hyposulphite. Measured squares of suitable size (say carte-de-visite) of the mounts to be tested are then cut into narrow slips lengthwise, introduced into test-tubes, and covered each with a measured ounce of pure distilled water. The cards should be left immersed for twelve hours, or longer, to afford time for a full solvent action to be exerted, and for the liquids to diffuse out from the compact structure of the cards. Having then arranged in a stand a series of test-tubes of about the same calibre, a small quantity of the blue iodide of starch solution is poured into each to the same height, and the liquids to be tested are added in similar quantities (say half a fluid ounce in each case), reserving one tube as a standard of comparison to be diluted with the same bulk of pure water. By inspection of the whole series it is easy to see whether any bleaching action occurs; and should this be the case, an inference may be drawn as to the amount of hyposulphite contained in the cards under examination, by comparison of the several tints with that of the standard tube. It should here be mentioned that the liquids to be tested must be employed cold, for a slight increase of temperature serves to diminish the sensitiveness of the reaction; in fact, the blue iodide of starch itself becomes temporarily bleached upon the application of heat. Proceeding in the manner just now indicated, I tested upwards of twenty samples of cardboard, with the following results: The weights were previously taken in each instance as a rough indication of the substance of the card; but, as will presently be seen, the enamel mounts contained so much mineral matter that their weights must have been out of proportion to the observed thickness. All were uniformly cut to the carte-de-visite size,  $2\frac{1}{2}$  by  $4\frac{3}{8}$  inches:—

No.	Description.	Weight— Grains.	Amount of Hypsulphite.
1 ...	White enamel carte-de-visite ...	63	... none
2 ...	Yellow enamel stereo mount ...	—	... small
3 ...	White Bristol board ...	59	... large
4 ...	Cabinet mount, white ...	55	... large
5 ...	Carte-de-visite mount, white ...	44	... moderate
6 ...	Cream-laid carte-de-visite ...	48	... trace
7 ...	Do. thin ...	37	... small
8 ...	Mounting board, cream colour ...	67	... none
9 ...	Do. pale buff ...	70	... small
10 ...	Do. buff (thick) ...	87	... moderate
11 ...	Do. neutral tint ...	46	... large
12 ...	Do. pale green ...	48	... very large

It thus appears that two samples only out of the twelve were free from hyposulphite, four contained quantities too small to be pronounced hurtful, and the other six were impregnated to an extent sufficient to justify their rejection for photographic purposes. The greatest difficulties are encountered in the selection of white cards, since the material of which they are made requires to be fully bleached, and hence the use of a greater proportion of hyposulphite afterwards applied as antichlore. The cream-coloured mounting-board appeared to present the natural colour of the best rag pulp, and may not have been subjected to any bleaching process, and consequently not required any after treatment with hyposulphite. This quality may therefore be expected to furnish the most reliable material for mounting photographs.

In the case of the neutral tint, another experiment was made after separating the three principal layers of which this cardboard was composed, and the source of the hyposulphite was found to be in the white paper backing thus:—

	Weight— Grains.	Hypsulphite.
Front layer, neutral tint paper	47	... trace
Coarse intermediate pulp	48	... small
White paper backing	32	... very large

This result was confirmed by a similar examination of one of the buff cards, which also contained most of its hyposulphite in the white paper backing. If such a card were left exposed for any length of time in a damp atmosphere the hyposulphite would, no doubt, ultimately become diffused throughout its entire structure; but the above facts show most conclusively that in the ordinary process of manufacture this distribution of a soluble impurity only partially occurs.

Very instructive results were furnished by an analytical examination of the mineral matters entering into the composition of the board, and I was surprised to find that the stiffest and apparently best quality of card contained a liberal amount of Paris white (sulphate of lime), to which no exception can be taken. The white enamel card, No. 1, left on incineration 28 per cent. of white ash, composed chiefly of a mixture of sulphate of baryta and China clay (kaolin), with a small quantity of Paris white. There was no zinc or lead pigment in this material, and the absence of the latter is an important consideration, since lead enamels so soon become sulphuretted. When the requisite degree of whiteness can be imparted by mineral pigments, there should be no necessity to resort to the processes of bleaching, and for such admixture no better material can be selected than the inert baryta-white, which is absolutely insoluble, and incapable of decomposition by ordinary chemical reagents, and is, moreover, to be had of good quality at a low cost. Ultramarine was detected in the green card, No. 12; and the substratum of the neutral tint, No. 11, also contained some imperfectly mixed with the pulp. This blue pigment owes its colour to sulphur-compounds, which are known to tarnish bright silver surfaces, and therefore may be expected in time to have an injurious influence upon the reduced silver entering into the composition of the photograph. Two of the cards, Nos. 9 and 10, of which the former was undoubtedly the higher quality, left, on burning

freely in air and afterwards in a platinum crucible, 12.2 and 7.6 per cent. respectively of ash, which was almost entirely sulphate of lime. Several of the cards were tested for alkaline chlorides, but traces only of these salts were detected.

Since MM. Davanne and Fordos have pointed out the dangers attending the use of Dutch gold and bronze-powders for embellishing photographic mounts, it may be of interest to know that a dilute solution of nitrate of silver enables us at once to distinguish between the true and spurious gold. Whilst gold itself retains its brilliancy, and remains quite unaltered upon moistening with the silver solution, the copper, zinc, tin, and other base metals contained in the bronze substitutes, effect the immediate reduction of the silver in the form of a dark-grey or nearly black pulverulent deposit.

Series II.—Tinted mounting-boards, of various colours, three-sheet thickness, all hacked with white paper of same quality.

No.	Description.	Weight— grains.	Amount of hyposulphite.
13 ...	Cream colour...	44	trace
14 ...	Do. slightly darker	42	none

Series III.—White cardhoard, of two qualities.

Description.	Weight (in grains) of the carte-de-visite size.	
	Best.	Seconds.
Three-sheet	38	40
Four-sheet	52	57
Five-sheet...	75	74
Six-sheet	96	88

All these cards were found to be comparatively free from hyposulphite of soda. They were tested by means of an iodo-dextrine solution containing about 1 grain of iodine (with iodide of potassium) and 100 grains of dextrine in a pint of cold water. The claret colour of this solution is bleached by hyposulphites with as much facility as in the case of iodide of starch. The solutions should be quite cold at the time of testing, since the colour of this dextrine compound is temporarily discharged by heat in the same manner and with even greater facility than the blue iodide of starch.

Woolwich, May 2nd, 1868.

## PHOTOGRAPHIC PRINTING IN SILVER, THEORETICAL AND PRACTICAL.

BY W. T. BOVEY.

SINCE the publication of my last article, enquiries have been addressed to me concerning the method to be observed for keeping the nitrates of soda and silver bath up to working strength, it being obvious to the most inexperienced that the usual specific gravity test is inapplicable to the sensitizing solution prepared by the formula I advise.

In reply to the queries alluded to, I cannot do better than quote an extract bearing on the subject from my paper published in the YEAR-BOOK, supplementing the same by pointing out a sure and certain test that all who have eyes may with ease understand. "To keep the bath up to working strength proceed as follows:—Commence operations by mixing enough solution to fill two bottles, numbering each respectively No. 1 and No. 2. No. 1 to be selected for daily use, No. 2 for replenishing waste. When sufficient paper has been floated for present use, filter the working bath back into its proper vessel, and, after all has passed through the filter paper, fill the bottle up to the neck with the replenishing solution from bottle No. 2. By the adoption of these simple means the bath, as a rule, may be kept in good and reliable working condition for any length of time. Should discolouration occur, a little moist kaolin dropped into the bath will remove it." The quantity of

waste in a great measure depends on the care taken in removing the paper from the bath; it is therefore within the limits of possibility, that when excessive caution is observed, the waste will not be sufficient to enable the fresh solution added to keep the bath in good working order. Such will be made evident at once by the appearance of the albumen surface when dried. An albumen surface, when submitted to the action of the silver, soda, and sugar solution, and subsequently dried, should exhibit a peculiar lustre, or bloom (proof that no albumen has been absorbed by the bath); if the glaze, such as I have described, be absent, and its absence is due to an over-weak silver bath, this last will rapidly discolour, and to repair matters a few crystals of silver nitrate must be added directly the discovery is made.

A certain wise contemporary, whose errors I have on more than one occasion had occasion to mention, still persists in advising his clients to steer clear of weak printing baths. He won't have nitrate of soda, and sugar he—perhaps for the first time—abominates. But, in all sincerity, I beg of all my readers to test the matter for themselves. I have done so exhaustively, and can with certainty and a clear conscience advocate its use; and, as a further argument, I might add, that many of the acknowledged finest prints exhibited at the hall in Conduit Street in November last were, to my knowledge, printed by the method I am describing.

And now for a word or two on the chemicals to be employed. In these days of cutting competition, a dealer, even in photographic chemicals, must be possessed of strong moral courage to enable him to resist the temptation to underbid his neighbours, and it unfortunately happens that chemicals afford a field for the exercise of adulteration free from any probability of detection. I would therefore advise my readers to seek—as I find—cheapness in the dearest market, for I hold that where a fair profit is realized by a dealer, as a rule, he would prefer rendering a pure to an adulterated article; and it may be worth mentioning that the mixtures of silver recently advertised afford a greater profit to the vendor than the sale of an equal weight of pure nitrate of silver, which salt, being composed chiefly of a noble metal, cannot, and never will be, sold under the value the metal can at any moment realise in the bullion market. My advice, therefore, is, to purchasers of nitrate of silver, don't be tempted by low prices, but buy of respectable honest dealers, who demand a fair price, and stick to it in spite of competition. The price I pay for the article is 3s. 5d. per ounce in quantities of not less than 50 ounces, and find it cheap in the money. For smaller quantities an addition of twopence per ounce is made. The nitrate of soda must be strictly pure, otherwise I cannot answer for the success of the formula I have advised, as it sometimes happens that the nitrate of soda as sold by the chemists is mixed with carbonate of soda; the result of such admixture is the weakening of the bath by the decomposition that occurs, and which is brought about by the carbonate of soda. The carbonic acid combining with the silver precipitates carbonate of silver, leaving in solution an unneeded addition of nitrate of soda. I have, however, found no difficulty in procuring the pure article in London, but the failures that have arisen from the source pointed out induces me to ask an observance of caution. The sugar may be extracted from the domestic sugar basin, whilst the requisite quantity of water can be drawn from the well or local water-works. Should the water, however, be charged with an excess of inorganic matter, it is advisable to boil the water before applying it to photographic uses.

It may appear superfluous for me to offer advice or directions concerning the operation of floating, but little things help to make mountains, and a word or two in the direction indicated may to some prove profitable. When the sensitizing solution has been carefully decanted into the dish, take a strip of albuminized paper, edgeways, and pass the lower edge of the paper lightly over the surface of the

liquid. This operation removes dust and scum, and stains on the surface of the sheets are thus prevented. When a quarter sheet only is sensitized at time of floating, with the finger and thumb of each hand seize the paper at the opposite corners. The corner held by the left hand should be the first laid on the solution. The paper, kept slightly arched by the right hand, must then be quietly placed on the bath in such a manner that all air is driven before it. To sensitize a sheet of paper in its uncut state, place the centre of its nearest end between the lips, seize the corners of the opposite end firmly between the fingers and thumbs, and lay that end carefully on the bath about midway of the dish; then, by lowering the head, and moving it towards the dish, the paper is pushed forwards, and, with a sliding motion, the whole surface is gradually brought into contact with the solution. A batten may be then placed across the dish, and when the time of floating expires the corners of the paper should be raised, pinned to the batten, which acts as a support during removal, and to which the paper must remain attached until dried; or, should it be preferred, the paper might be removed from the dish without the aid of such batten; in such case the paper should be spread corner-ways across a roller, and so left to dry. The use of American clips for whole sheets of paper is objectionable on account of the liability the paper has to tear, or provokingly curl in such a manner that the wet surface is brought into contact with the back. If the temperature of the drying-room is increased by artificial heat, the paper should be removed from such room, and kept for a short time in a temperature and atmosphere similar to that to which the paper will be exposed while printing. Neglect of this last hint will cause loss from the cockling of the paper whilst under pressure in the frames, occasioned by the expansion of the fibre if the air be damp and the paper dry, or contraction if the atmosphere is warm and dry and the paper damp. When a mucilaginous substance is employed in connection with a sensitizing bath it should never be added in excessive quan-

tity, as it causes a distinct line to appear on the surface of the paper at every pause during the laying it on the solution.

And here I dismiss the silver bath to fill the frames, which must supply matter for my next. The subject of printing I shall deal with in its entirety, offering practical instructions how to perform every known method of producing varied results.

In conclusion, I must ask the indulgence of my readers on account of the delays that occur in the appearance of my lessons; but the reason why is briefly told: after my daily laborious work is done, I find, at times, a weary body but ill adapted for aiding or encouraging mental labour.

## PICTORIAL EFFECT IN PHOTOGRAPHY;

BEING LESSONS IN

COMPOSITION AND CHIAROSCURA FOR PHOTOGRAPHERS.

BY H. P. ROBINSON.

### CHAPTER XV.

"How great a share variety has in producing beauty may be seen in the ornamental part of nature. All the senses delight in it, and equally are averse to sameness. Yet, when the eye is glutted with a succession of variety, it finds relief in a certain degree of sameness; and even plain space becomes agreeable, and, properly introduced and contrasted with variety, adds to it more variety. I mean here, and everywhere indeed, a composed variety; for variety uncomposed and without design is confusion and deformity."—Hogarth.

### VARIETY AND REPETITION.

For the more easy comprehension of this chapter it would be well for the student to turn to the illustration given in the last—Wilkie's Blind Fiddler.

Notwithstanding the formality of the composition, the great quality without which no pictorial arrangement can be complete—variety—is present in a very marked degree. This is very noticeable in the disposition of the heads and leading points, as will be seen at a glance by the following diagram, in which they are set forth; as will also the pyra-

midal forms of the groups, and the way in which they fall in with and harmonise one another, continually piling up until they form one great irregular pyramid, supported by

the group of dark objects in the front. The extreme care Wilkie has taken to get his pyramid complete will be seen in the disposition of the fiddler's bundle and stick on the

one side, and the spinning-wheel on the other. Every variety of aspect in the heads is given, from the full face of the grandfather to the back of the head of the fiddler's son warming his hands at the fire. Every position is represented, standing, stooping, leaning, sitting, lying, as well as every degree of expression, from lively action to repose, "from grave to gay, from lively to severe;" and every age, from the octogenarian to the infant, youth being directly opposed to age in the centre of the group.

That variety is a necessity in good composition is so apparent that it need scarcely be dwelt upon at any length. It must be obvious that the reverse of variety—that is, monotony—would be fatal to a picture. One definition of composition might be that it teaches the proper use of variety. A line running in a given direction must be balanced and opposed by a counteracting line. Full faces in a group should be varied with three-quarter and profile heads. A line of heads "all of a row," as is too often seen in photographs even by the best photographers, is jarring to a sensitive taste, and is an offence to art. So also with figures dotted about a landscape without purpose, disturbing repose by directing the eye to objects which are out of all harmony with the view represented.

Variety is one of the chief sources of picturesqueness and beauty. This quality alone would make a dead flat interesting. The ever-varying lines of the waves—varying, however, according to regular laws—make the level and otherwise tame and monotonous ocean a constant fascination. No tree, however finely grown and vigorous, presenting an unbroken mass of foliage will interest the artist so much as others, inferior although they may be in size, but presenting variety in their outline and intricacy in their details. Without variety of form there cannot be variety of light and shade.

Notwithstanding the absolute necessity of variety as one of the chief sources of beauty, it may be, and frequently is, carried to excess. All great painters have guarded against this by introducing the opposing element to variety—repetition—repetition as an echo, not that resemblance which produces monotony. Picturesque effect will allow, and demands, a greater amount of variety than beauty, which appears to require a greater amount of simplicity for its success. Variety of attitudes should be studied for the sake of contrast; but simplicity, especially in photographs, must not be lost—the peculiarity of the art itself supplies sufficient intricacy and detail. No amount of ingenuity in varying the positions and aspects of the figures will compensate for loss of simplicity and repose. Photography does not admit of much action. In painting, the model is forgotten; in photography it is different. It is well known to everybody that the figures represented actually stood for some seconds in the attitude shown—except, indeed, in instantaneous pictures, where art often has to accept much from chance (we cannot get away from that fact, even if we desired to do so)—whilst painting or drawing is a representation of something that need not have been seen for more than an instant by the artist; indeed, it is not necessary to the enjoyment of a painting to know that the original ever existed.

Simplicity, symmetry, and uniformity, strange as it may appear, are not antagonistic to variety, but are, in the extensive scale of nature, highly conducive to it, especially in scenes composed of many objects. Uniformity in a single figure will produce monotony; but in a scene composed of many figures it will add to the variety, for if the greater number of figures be irregular and varied, the introduction of repetition in some of the objects will actually increase the variety. This is beautifully illustrated in the Blind Fiddler, in which that "uniformity in variety" which is necessary in a perfect work of art is finely shown. The following diagram exactly repeats the lines of the fiddler and the woman with the child seated precisely opposite to him.

It will be seen that the position of the body is the same in each—stooping a little forward, with the head bent down;

the lines of the arms, the legs, and the chairs exactly correspond, and the line produced by the child's arm reaching up

repeats the line of the fiddle-stick, while both figures, although different in sex, wear caps; the lines of the dress even, especially above the arms, are symmetrical, and in both cases the back leg of the chair is concealed. This uniformity is not accidental, but must have been produced deliberately and with a purpose. There are other similar examples of repetition in this perfect composition; for instance, the boy imitating the action of the fiddler with the poker and bellows. The delight of the human beings repeated in the face of the dog, and, if you like to be fanciful, the rude art of the fiddler echoed in the rude art of the caricaturist in the picture of the soldier on the wall.

#### OBSERVATIONS ON THE EMPLOYMENT OF SULPHOCYANIDES.

BY M. CIVIALE.\*

IN the summer of 1867 I fixed about seven hundred photographic prints by means of the sulphocyanides of potassium and ammonium. I employed them both indiscriminately, and found that three pounds of material was sufficient to tone and fix the number of pictures referred to. The mode of operating which has yielded me the best results is summed up in a few words.

The print is toned a little less vigorously than when hyposulphite of soda is used for fixing; it is washed in two changes of water as it comes out of the printing-frame, and is then immersed for a period of fifteen minutes in a 20 per cent. solution of sulphocyanide. The print loses its intensity in this bath, and assumes a yellowish colour; on its exit from the same it is again washed in two or three changes of water, and then placed in a gold bath rendered slightly acid and containing 25 centigrammes of gold to every litre of distilled water. As soon as the tone of the prints begins to deepen and becomes of a greenish tint mixed with blue and sepia, it is taken out and transferred to a 35 per cent. bath of sulphocyanide, where it is allowed to remain until it has assumed the desired intensity and tone: a prolonged sojourn in the bath causes the prints to assume first a blue and afterwards a bright rose colour. By the employment, therefore, of a bath of this description, pictures possessed of three different tones may be obtained in the following manner.

When the print has become of a black tone, the lower portion of it is removed from the bath: the middle of the picture, representing the more distant portions of the landscape, then assumes a blackish-blue, and afterwards a greyish-blue colour. Two-thirds of the print are now withdrawn, and the part corresponding to the sky only allowed to remain, when a rose-tint similar to that observed by the setting of the sun is obtained on this part of the picture.

Four or five prints may thus be manipulated at the same time and in the same bath; but with a larger number it is impossible to render the necessary attention. The baths may be used until completely exhausted, when they are again

\* Read before the French Photographic Society.

made serviceable by the addition of a further quantity of sulphocyanide.

The very simple manipulations which I have here indicated are easily carried out, and if a somewhat longer time is required in their execution than in the hyposulphite method, this inconvenience is largely compensated by the freedom from stains and the necessity of much less washing after fixing by the sulphocyanide process.

A more rapid process, which likewise gives good results, may be employed if desired. Into a litre bath of sulphocyanide (20 per cent. strength) is poured an aqueous solution of 25 centigrammes of chloride of gold rendered slightly acid: the precipitate formed at once redissolves. The proof, after being taken from the frame, is washed as before, and plunged into the bath, in which four or five sheets may be placed at one time. As soon as the toning is sufficiently marked the sheets are withdrawn, and immersed in a 35 per cent. solution of sulphocyanide, and the operation of fixing proceeded with as before. The bath will last for any length of time if the gold and sulphocyanide is renewed from time to time. Leptographic and collodionized papers may be treated in the manner here indicated with very great success.

I will conclude by submitting to the inspection of the Society a print toned and fixed with sulphocyanide, which has been exposed in a window for the space of three months, a portion of it having been screened from the action of the light during that period. No difference is perceptible between that portion of the print which has been covered up and the remainder, which was constantly exposed to daylight.

#### COLLODIO-CHLORIDE.

BY WILLIAM A. TERRY.\*

In a conversation some months ago with Prof. Seely, of the late *American Journal of Photography*, I mentioned results of some experiments, and conclusions derived from them, on the nature of collodio-chloride, which he thought might be of interest to many, and which have been recently recalled to mind by an article of Mr. Lea's on dry plates, and his remarks on collodio-bromide.

When the porcelain picture first began to attract attention,† I procured some collodion from New York and commenced making them; the first bottle I used made very good prints, but that was soon used up, and the next sent me was of a different make, and was not satisfactory. I wrote to my stock dealer for more like that previously sent. He replied, that there was no more in market; that the kind sent last was in common use; and finally sent another bottle which, he said, was fresh, and he knew was good. This on trial proving to be no better than the other, I made some myself with but indifferent success. Soon after I called on friends in the business in other places, and found many of them complaining of the same troubles.

The trouble was a whitish mistiness that degraded the purity of tint and the surface quality of the print, so that, instead of a brilliant surface-colour, which should have been produced, the picture appeared sunk into the body of the collodion film and covered with haze, having something the appearance caused by excess of ammonia on an ammonio-nitrate print, or the same print very much over-toned.

This appearance was as plainly seen before as after toning, and was evidently caused by some defect of the collodion. I tried the addition of various reagents and organic compounds with some success, but soon became convinced that the theory which regards collodio-chloride as being simply chloride of silver suspended in collodion was erroneous, and that it was in reality a compound of chloride of silver and collodion, of such a nature that the chloride of silver was held in a peculiar state of solution instead of suspension.

My attention was first directed toward this view by noticing that all samples of collodion that produced the best prints had a humular opalescent look, and but little colour by reflected

light, and in small vials appeared transparent and of an orange or red colour by transmitted light, even when containing two or three times the quantity of chloride of silver contained in other samples which were opaque. This I thought could not be the case if the chloride was simply in suspension; and as I noticed that all the inferior kinds in my possession were quite white, creamy, and opaque, I determined to test the matter by a few experiments.

First. I precipitated a quantity of chloride of silver in a solution containing an excess of nitrate, in order to leave the chloride as sensitive to light as possible; then, after decanting the liquid, drained and washed the chloride in pure alcohol to remove the water; after this the requisite quantity of collodion, containing 2 or 3 grains to the ounce of nitrate of silver, was poured upon it in a bottle of sufficient capacity to allow of its being violently agitated by shaking. After being sufficiently shaken the citric acid was added. This collodion now exactly resembled in appearance that which I had received from New York, and which was so satisfactory; being thick, white, creamy, and opaque, the chloride did not subside on standing. I found prints made with this collodion to be, as I expected, milky, hazy, and feeble. I tried various proportions of free nitrate without producing much effect, and concluded finally that chloride of silver suspended in collodion was worthless for printing purposes.

Reasoning on the view that collodio-chloride was a definite compound of chloride of silver with some constituent of collodion, I thought success might probably be best attained when all the constituents were in perfect solution in collodion, and mixed suddenly at a low temperature; accordingly, I took a given quantity of plain collodion and divided it into three unequal portions: in the first and largest I dissolved sufficient nitrate of silver to make a strength of 8 grains to the ounce of the whole; in the next largest I dissolved chloride of strontia sufficient for about  $2\frac{1}{2}$  grains to the ounce of the whole quantity of collodion, and enough citric acid to make about 1 grain to the ounce in the third and smallest portion. After shaking and standing until each was completely dissolved, I cooled them to below 60° Fahr., then poured carefully that containing the chloride down the side of the bottle upon that containing the silver, being careful not to mix them until the whole quantity was in the bottle, when, by shaking suddenly, they were mixed almost instantaneously. The citric acid was added in the same way. This collodion was almost colourless, having only a slightly milky and opalescent appearance, and this was chiefly caused by the reaction of the citric acid, before the addition of which the collodion was nearly as transparent as that containing only nitrate of silver, which always communicates a peculiar and characteristic appearance to plain collodion.

On making prints with this collodion I found it very sensitive, giving a remarkably brilliant surface-colour, but requiring a longer exposure to produce bronzing than other kinds in my possession, this fact being due to the very small excess of nitrate of silver. In subsequent experiments I found that increasing the excess of nitrate increased the intensity of the print up to a certain point, but that past this point the collodion rapidly deteriorated; and also that as the intensity increased the surface-brilliance was apt to diminish. The point of greatest intensity was usually reached when the collodion contained 2 or 3 grains of silver to the ounce in excess, being varied somewhat by the absolute amount of the whole; I found also that the keeping quality varied in proportion to the excess of silver—that containing most silver soon changing to an opaque white, and making hazy and feeble prints, particularly if kept in a warm place. Chloride of strontia was objectionable on account of its tendency to form crystals in the collodion at a low temperature, although previously completely dissolved—that is, before mixing with that containing silver; chloride of calcium is not liable to this objection; I did not test them in other respects. This matter of solubility in alcohol is one of considerable importance in the manufacture of collodio-chloride; if each ingredient is not in perfect solution at the time of mixing, not only loss ensues, but the result will be irregular and uncertain. I next tried the effect of different salts of silver. I made a compound salt by acting on fulminating silver with a mixture of the nitrates of silver and ammonia; the salt thus formed resembled ammonio-nitrate in many respects; it crystallized readily, in long needles; I have frequently found them 2 or 3 inches in length, and dissolved so freely in warm alcohol as to form a solid mass on cooling, but different from ammonio-nitrate in one very important respect; for while ammonio-

\* *Humphrey's Journal*.

† The use of our collodio-chloride process is much more extended in the United States than in this country. Opal pictures there form an important element in the professional practice of portraiture.—Ed.

nitrate added to collodio-chloride causes it to turn to a dark-grey colour in a short time, I have collodion made with this salt which has been kept over two years, and is now as white as when new, and has changed less in other respects than common collodion would have done in as many months.

The prints made on this collodion were of a warmer tone than ordinary, being a bright-red instead of blue; they also lost less of intensity in toning; they had also a more brilliant surface-colour, with a large excess of nitrate of silver; and, on the whole, I preferred this collodion to any other.

Fulminating silver, which is a compound of silver and nitrogen, should not be confounded with fulminate of silver, which is a compound with fulminic acid. The former is sometimes formed in small quantities in the manufacture of ammonia-nitrate. I have known the cotton filter which had been used for ammonia-nitrate to explode on being disturbed after getting dry, and set fire to the contents of the waste-box. It is an exceedingly dangerous compound, being apt to explode if handled while wet, and almost certain to explode with fatal violence as soon as dry, resembling somewhat the iodide of nitrogen.

Some years since I was suddenly awakened about midnight by a loud explosion. On rushing into an adjoining apartment I found that a quantity of iodide of nitrogen, which had been reposing quietly for some weeks at the bottom of a small glass jar or bottle covered with water, had suddenly vacated its previous quarters, and taken up a position on the ceiling overhead, where it covered a space of ten or twelve feet, more or less. An incessant series of small but deafening explosions, seeming to testify to both rage and satisfaction, occurred as fast as the porous plaster absorbed the moisture; the room was filled with dense vapours of iodine, so as to render it almost impossible to breathe, or even see. Fortunately, I had a quantity of hyposulphite at hand, which was soon in a basin of water; a towel saturated and applied soon brought the enemy to terms before any more serious consequences ensued. Many other compounds of nitrogen are similarly or even more dangerous—the chlorido and the compound with gold, for instance—and had better be avoided. On this account I prepared a different salt, which answered the purpose nearly as well, although collodion containing it would not keep so long as the other. The mode of operation, as nearly as I recollect, was as follows:—

Into about two drachms of the strongest aqua-ammonia I dropped carefully small crystals of nitrate of silver until the liquid became muddy; then a few grains of nitrate of ammonia, or a drop or two of nitric acid was added until it became clear again; nitrate of silver was then dropped in again, until the liquid was saturated at a temperature of about 180° or 200°; about an ounce of alcohol was then added and heated rapidly to the boiling point; during which time the clear solution should pass through various shades of brown and red, until finally nearly black; on cooling, a light flocculent black deposit should subside, leaving the solution colourless, and of sufficient strength to crystallize in a solid mass below 60°.

A few drops of this solution added to ordinary collodio-chloride changes the colour of the print, giving more brilliant surface qualities, and preventing the milky haziness even when the excess of silver is considerable.

Care should be taken not to over-print too much, as the print does not bleach as much in toning as is usual.

Poor collodion may even be restored to tolerably good working qualities by means of this solution.

I have even made prints of the colour of carbon prints, and which required only fixing without toning, by a modification of the above process; but as I do not consider that as of any particular practical value, I shall not describe it at present.

## Proceedings of Societies.

### FRENCH PHOTOGRAPHIC SOCIETY.

The last Monthly Meeting of the Society was held on the 3rd ult., M. BALARD, President, in the chair.

M. FRANK DE VILLECHOLES submitted, in the name of M. Chambay, samples of unglazed photographic paper suitable for enlargements and also for ordinary work. The material, which

is twice as rapid in its action as albuminized paper, has received no glazing or coating of any description, but owes its particular qualities to the employment in the pulp of a mixture of certain ingredients introduced therein; the surface presented being rough in character, the operations of retouching and colouring are easily performed. It is sensitized with a 15 per cent. solution of nitrate of silver, of which half is first treated with ammonia until the precipitate has completely dissolved, and then added to the remainder, which is slightly acidulated with nitric acid.

M. SOULIER exhibited a large number of carbon prints which had been prepared by what he regarded as a modification, or rather simplification, of Swan's process.\* A glass plate was coated with a film of very thin collodion, and as soon as this had set a dilute solution of gelatine was poured over it to form a second layer; on this was spread the sensitive compound upon which the photographic image was subsequently to be formed. When perfectly dry the whole is removed from the glass, and a homogeneous film of considerable rigidity is obtained, which may be manipulated with safety. The exposure takes place from the collodionized face, as in Swan's process, and the operation of washing is then proceeded with in the ordinary manner. No transfer of the print is requisite, but when properly developed it is mounted upon cardboard in the ordinary manner. M. Soulier likewise presented to the Society a negative taken instantaneously upon albumen, representing several steam boats on the Seine in motion.

M. BLANC made a few remarks in reference to the development of dry plates. He stated that it might be laid down as a general principle that the development of the lights of a picture is prejudicial to the development of the half tones, unless the lights have been somewhat over-exposed. It is for this reason that with two exposures of equal duration more detail is obtained in the shadows when the sun is obscured as when working with full sunlight, and that by alkaline development shorter exposure may be given than by the ordinary method; the silver which forms the image being at once decomposed, and unable, therefore, to exercise its affinity for the lights of the picture. For the same reason it is necessary to allow the lights of a picture to become solarized, so that their great affinity for reduced silver may be weakened, and also that a slow development is required for subjects presenting much contrast. With reference to slow development, M. Blanc communicated a method which he believed was not generally known. By placing a dry plate in a very dilute alcoholic solution of pyrogallie acid containing no nitrate of silver or alkali of any kind, an image may be gradually but very effectively developed.† It is very probable that the silver precipitated in this case is due to a trace of nitrate of silver still resident in the plate, which a washing of even the most careful description has failed to remove; decomposition taking place at once, the activity of the lights does not prejudice the development of the half tones, and hence a very gradual result, similar to that obtained by alkaline development. The mode of proceeding is a very slow one, four-and-twenty hours being scarcely sufficient for its completion; but what is lost in rapidity is gained in power, and it is in this direction M. Blanc thinks that photographers desirous of securing rapidity of action in dry plate photography should direct their attention, for the purpose of discovering some new developer. In chemistry the most feeble affinities produce great effects if the necessary time is allowed for their action; and what is the development of a negative but a chemical action? An exposure of the most rapid description suffices to secure a feeble impression, and to create, therefore, a feeble affinity for the reduced silver; by giving more time to the operation of development, varying its details, and employing new materials, the desired result might possibly be attained.

M. DE CONSTANT-DELESSERT forwarded a few copies, for distribution among the members, of his pamphlet on dry plate processes. He recommends therein the employment of the gum and coffee processes.

M. CIVIALE communicated a paper on the Employment of Sulphocyanides (see p. 223.)

M. DAVANNE brought under the attention of the Society

\* It will be seen that this process, supposed to be a modification of Mr. Swan's, is simply that which Mr. Swan first described before the Photographic Society of London, and which is fully detailed in this specification.—*Ed. PHOTO. NEWS.*

† This is surely but another mode of applying the plain pyro developer of Mr. Mudd, or rather Mr. Wardley, well-known in this country, and practised for years.—*Ed. PHOTO. NEWS.*

some of M. Marion's new transparent pellicle, and described its uses.

M. DESPAQUIS described the process employed by himself for the preparation of carbon prints on *collodion-cuir*, and gave a practical demonstration of his method of developing and mounting the prints.

The Society thanked M. Despaquis for his communication, and requested him to prepare a description of the process for publication in the *Bulletin*.

The proceedings then terminated.

#### OLDHAM PHOTOGRAPHIC SOCIETY.

THE Ordinary Meeting of the above Society was held on Thursday, the 30th inst., the President, Mr. JOHN GREEN, in the chair.

After the minutes of the previous meeting had been read, Messrs. John Dalton and Wm. Fernley were elected members.

Mr. BEVERLEY then read a short paper on the Dry Plate Process, which will appear in our next.

There being no other business, the meeting was brought to a close.

### Correspondence.

#### SEL CLEMENT.

DEAR SIR,—I presume you have taken the course of inserting the letter from "The Maker of the Sel Clement" merely as an act of courtesy to a foreign correspondent, who, although professing to be a chemical manufacturer, does not write like a chemist.

The writer says, "For me, substances containing carbon are not the only ones that are organic; but I consider as such all those which contain either hydrogen or nitrogen." Impossible! Has hydrochloric or nitric acid ever been included in the list of organic bodies? I challenge the writer to quote any authoritative statement to this effect. On the contrary, the existence of carbon is a *sine qua non*; without it no organic compound can be built up. Dr. A. W. Hofmann's apt definition of organic chemistry declares it to be "the branch of science which treats of the migration of carbon."

Again, it is suggested that "the nitrous fumes formed during the combustion have reduced the nascent carbonic acid into carbonic oxide, they themselves being converted into nitric acid." This view is quite opposed to well-ascertained facts: simply because nitric acid vapour, when heated in a combustion tube, splits up into red nitrous acid and free oxygen; and, in the presence of this latter, it is impossible for a *reducing* action to be exerted upon the carbonic acid. Your Paris correspondent takes exception to the form of apparatus used in my experiment, and asserts that it "was not properly arranged to show any trace of carbon;" whereas I took especial pains to prove the fact that it did furnish evidence of carbon when I purposely introduced a trace of sugar, after the Sel Clement alone had failed to show any indication of the existence of an organic component by the production of a white precipitate in the lime water.

The occurrence of nitrate of magnesia and of a large amount of water, as essential ingredients of the "Sel Clement, or Preservative Nitrate of Silver," is virtually conceded.—I am, dear sir, yours, &c.,

THE ANALYST.

May 1st, 1868.

#### THE PANORAMIC STEREOSCOPE.

DEAR SIR,—While thanking you for the kind notice in your Journal of the panoramic stereoscope, we shall feel much obliged if you will permit us to correct an error as to the assumption on which the new form is based. This you state to be that "the angle of natural vision horizontally is only one half of the vertical angle." We did not intend to convey that impression. What we really meant was, that while the size of two pictures which can be united stereoscopically is limited in the horizontal direction by the fact that their centres must be as nearly as possible opposite the pupils of the eyes, in the vertical direction it is limited only by the angle of natural vision, which practically admits of the use of a picture nearly double

the height of the width between the eyes. Our aim has been to modify the mode of taking and the instrument for viewing stereographs so as to take advantage of this fact.—We remain, yours, &c.,

W. HARDING WARNER.

London, May 5th, 1868.

ROBERT MURRAY.

[We have pleasure in giving insertion to the above explanation; but we must point out to our correspondents that the sentence to which they take exception is not ours, but theirs, or that of Mr. Warner, as in making an allusion to such a claim we felt it right to do it in the words of the claimant. The description of the instrument now before us, in Mr. Warner's handwriting, runs thus:—"The inventors have discovered and taken advantage of a new and important feature in optics hitherto overlooked by all makers of stereoscopes, viz., that the angle of vision horizontally is only one half of that vertically." Whilst fully recognizing the practical value of the new instrument for many purposes, and the satisfactory results it gave, we felt it a duty to take exception to what appeared an erroneous statement of principle as the basis of an excellent invention.—Ed.]

#### MODIFIED HONEY PROCESS.

SIR,—Thanking your correspondent, Mr. G. Robert Fitt, for his description of a "Modified Honey Process," published in the NEWS of 24th April, 1868, I should feel very much obliged if he would give the quantities of honey and water respectively to form the syrup, also the proportion of pure animal charcoal required, and whether the plates will keep some hours after exposure before development without injury, and if they should be flooded with water, or what, before development.—I am, sir, truly yours,

M. N. L.

57A, Wimpole Street, May 5th, 1868.

#### PHOTO-LITHOGRAPHY.

SIR,—We feel very reluctant to encroach upon the space of a journal devoted to science only, with reference to personal affairs, but we cannot permit statements to be made which, if circulated, may find believers among those who are perfectly uninitiated in photo-lithography.

In your number of April 24th, 1868, you made some remarks as regards the working of a "new process of photographing on stone;" and although you find the results excellent, and the application of photography most legitimate, yet you consider these results not to be examples of photo-lithography "as popularly understood."

You further speak of the results "on good authority," that the prints are the productions of a "silver process on a finely-grained stone, and the image is then worked with lithographic chalk," &c. But the "good authority" goes even beyond this in his observations, by stating before the Photographic Society that, "if he is not mistaken, the prints he has seen lately from a new process of photographing on stone" have been produced in the way described by you under the head "Griggs' Lithographic Process," and in which he states he obtained by the same means that he employed some four years ago; viz., by coating a grained stone with silver.

We do not know of any other house in England or on the Continent engaged at present in working commercially "portraits by photo-lithography," therefore we are compelled to come forward as the owners of the "new process of photographing on stone," for the purpose of answering and contradicting those statements.

An apprentice in lithography will be in a position to explain as to what the effects of lithographic chalk may be when being put upon a silver surface, or, indeed, any other surface but the cleanest surface of the stone itself.

We are fully alive as to the motives which prompted those statements, and therefore will confine ourselves simply to the declaration that our productions are the results of photographing direct on the stone with materials capable of yielding proofs in printers' ink only. We are not quite blind to the hints of your "authority" that he does not keep back useful information "selfishly," nor do we mind his allusions that he does not pride himself on "secret dodges," nor do we care for his pointed invitation to come forward and "give up freely the results of our labours." Nothing will induce us, beyond this letter, to be drawn into a controversy, for many and "obvious reasons." Suffice it to say that the means for obtaining lithographs by a

silver process "four years ago," or to-day, are not the only absurd experiments which have proved failures in the hands of your "authority."—We are, sir, yours respectfully,  
29th April, 1868.

DIMSDALE AND CO.

[We are glad to have the assurance of Messrs. Dimsdale and Co. that the excellent portraits they have recently issued are by a process of photo-lithography properly so called. The allusions to "motives," of which they are well aware, to our "authority"—of whom, by the way, they can know nothing—&c., are entirely beyond our comprehension; we have not the slightest idea of what they mean; but as our correspondents seem to think them necessary to their explanation, and they may have a meaning for some persons, we give them insertion, repeating that the points in the letter which are clear to us—namely, the assertion of the truly photographic character of their excellent portraits—can give us and photographers generally nothing but satisfaction.—Ed.]

### PHOTO-LITHOGRAPHY.

SIR,—As I am wishful to make some experiments in photo-lithography, will you oblige me with answers to one or two questions?

1. Is there any special advantage, besides the convenience of working, in the mode of producing an image on paper to be transferred to stone, instead of working directly on stone as in some of the earlier processes?

2. I see in a contemporary an intimation that as the object of treating a transfer with water is to swell the unaltered gelatine, cold water is necessarily the proper thing to apply, and not hot, and expressing surprise that the members of the Photographic Society present when Mr. Griggs read his paper showed such ignorance on the subject. I wish to ask if the object of applying water is to swell the gelatine, and, if so, for what purpose? I have always understood that the object was to remove the gelatine, not to swell it.

3. Is photo-lithography generally, or any part of it, protected by patent, or is it open to the public to practise without licence or patent rights having to be gained? If not, which process is free to the public?—Yours, &c., X.

[The advantages of the transfer process, besides convenience in working, consists in getting a greasy image direct on the stone. In most processes in which the picture is produced by working on the stone, the image is formed on the stone in some such substance as gelatine and bichromate, or bitumen, and thus it quickly wears out. 2. We fear it is the writer in question, and not any member who spoke at the meeting, who betrays want of familiarity with the operations of photo-lithography. If the object had been to swell up the gelatine, most folks know well enough that cold water would effect it best. But the object is not to swell up the unaltered gelatine; where hot water is used, the object is to dissolve the gelatine and remove it entirely. Where cold water is used, or rather slightly warmed water, as in Mr. Griggs' case, the object is not to remove all the gelatine, but only just such a surface as will effectually take away the ink except on the parts made insoluble by light. If the soluble gelatine were swelled to any appreciable extent it would interfere injuriously with the operation of transferring, by bearing off the unswollen inked lines from contact with the stone. 3. There are several patents for photo-lithographic processes; but the general features of all processes are open to the use of the general public without restriction.—Ed.]

### SOURCES OF SUCCESS IN OPERATING.

DEAR SIR.—Mr. McLachlan's remarks in your number of the 17th January are, if practical, extremely interesting to photography. It has always been an art in which much was obscured; there is no rule, so to speak, on which to work with success; suggestion after suggestion is made in your Journal; one upholds *this* to be correct, the other flatly denies it, and states *that* to be the proper way, and so on. But Mr. McLachlan steps out of the usual course, and challenges the public to produce by himself, *consequently*, a certain amount of pictures, and free from every blemish, with *success*! Every photographer knows it is possible, but in his experience has it ever happened that he could say the same? Consider, the number is large, and the amount of silver used is wonderfully small in proportion (see his letter, p. 400: 7 by 4 negatives with 2 ounces of silver,

and still plenty to spare). I shall be glad to see you comment upon it.

By the way, I was rather amused at the persistency of that idea argued about converting bad negatives into good ones, touching the negatives, &c.: not mere spots, but painting over it at a wholesale rate. Why not rather study your photo-rooms, look more to your light, your chemicals, than to producing artificial effects? I was very much pleased with Mr. Johnson's paper on "Natural Clouds in Landscape Photography." What further proof would you require in reading his account of Mr. Braun's pictures? As pictures they are perfect; as a commercial speculation they have paid handsomely. Another fault is often committed by using the argument that "the public won't have it so." In how many various ways does one hear that expression? It is to some degree true; doubtless a large portion of the public do not care much about the delicate and beautiful—or, perhaps, I might put it, they prefer the excessive contrast to the fine gradation—but it is not wholly to them the photographer looks for his earnings. Moreover, if he were to produce superior pictures, the mind of the public would, in like manner, be educated up to them, and they would in time be appreciated. Mr. Johnson's letter is upon clouds; it will apply to nearly every species of photography. A good photographer will turn out a good picture at the same place and time in which an inferior one will produce a wretched caricature.

A grand discussion has been carried on in your pages with regard to the photographs in the late exhibition, more especially to those of M. Adam-Salomon, which I should much like to see. From what I can glean, the lighting is thought to be the chief source of success. Whilst lighting undoubtedly has a great deal to do with it, I agree with "Ennel," that it is *judgment* which is most required. You mentioned some time ago some photographs exhibited which had an extremely picturesque and pleasing effect, yet these had all the lighting from *behind*, viz., the person taken thrown in relief. I do not remember ever having seen any such, but your remark says at once that it is not the *material*, but the way in which light is applied, which is conducive to success; i.e., your light may be north, south, east, or west; study the effect of each, and you will find each has its good effect; and, after all, it is the picturesque that is called for. To produce a portrait with every feature distinctly marked, every fold in the clothes sharply and softly defined, is good, but it is not everything. If one photographer (and there are some) can get that requisite, surely it is within the power of another to do it; the requirement is to make the best of what you have. I take it, in Mr. McLachlan's case, a knowledge of chemistry is indispensable. I shall look forward with eagerness to see more upon the subject.—Yours truly,

CEYLON.

Columbo, Ceylon. March 24th, 1868.

[As you will see, Mr. McLachlan has already made a partial statement, and will make a more perfect one shortly.—Ed.]

### Talk in the Studio.

SUGAR IN THE PRINTING BATH.—The Paris correspondent of a contemporary, giving a notice of M. Davanne's *Annuaire*, says that he "has a rap at Mr. Bovey" for having proposed "a little sugar in the nitrate bath." M. Davanne is represented as condemning the indefiniteness of the quantity described as "a little," and as failing to see how an organic substance having the power to reduce silver can preserve the whiteness of the sensitive paper. Somebody has blundered a little here. Mr. Bovey did not propose "a little" sugar, but, finding such a proposal made by an American photographer, he tried it, and gave photographers the benefit of his experience in the form of a definite formula, the value of which has been verified in his own practice and that of many photographers since. The paradox of a reducing substance having a preservative action was pointed out and discussed, with its probable solution, in our pages six months ago, when Mr. Bovey's recommendation to use sugar was first published.

COLOURED NITRATE BATH TO PREVENT "BLURRING."—Mr. Carey Lea proposes to prevent blurring from the light reflected by the back of the sensitive plate, by using a nitrate bath containing a neutral colouring substance, which makes the solution blood-red. The colour is washed away in the sub-

sequent operations, without further affecting the negative. Mr. Lea's article is compelled to stand over this week, but will appear in our next.

**OBITUARY.**—M. Hermagis, a photographic optician, whose lenses are well-known, died a week or two ago in Paris.

**LIGHT AND COLOUR.**—Here is a fact showing the influence of artificial light in the production of green colouring-matter. Some lilacs were placed for forcing in a heated cellar partially lighted with gas. Those leaves that were exposed to the light became green, as if they had been in the open air, while the remainder were etiolated. The fact is recorded by M. Ermins in a recent number of the *Revue Horticole*.—*Land and Water*.

**THE ROYAL DIARY.**—Messrs. Marion and Co. have just issued a series of landscape photographs to illustrate the Queen's book, "Leaves from the Journal of our Life in the Highlands." They are forty-two in number, and are so mounted that they may be bound with the original edition of the book they are intended to illustrate.

**THE AMERICAN PHOTOGRAPHIC CONVENTION.**—A very full report of the proceedings of the Convention of Photographers in the United States appears as a supplement to the *Philadelphia Photographer*, in which it fills thirty-two columns. Of these, 3,500 copies were ordered to be distributed amongst the photographers of the United States.

**USE OF MONOCHROMATIC LIGHT AS A MEANS OF DETECTING DISEASE.**—Photographers, says the *Scientific Review*, and other persons accustomed to make use of various kinds of light, have often alluded to the curious properties of monochromatic rays; i.e., rays of one colour. Thus, a spirit lamp burning alcohol saturated with common salt gives a ghastly hue to the features of the bystanders. We read in a recent paper by a Dutch physician, Dr. G. Schlegel, that this property has been made use of in China for many years as a means of distinguishing persons affected with leprosy. The virus can be thus detected in the blood of a person who has been infected with this dreadful disease only one or two days. By ordinary daylight it is impossible, at this early period, to remark any difference between the tint of his skin and that of a person in perfect health; but when the faces of both are lighted up by the flame of a spirit-lamp saturated with salt, whilst the face of the healthy person appears deadly pale, that of the individual affected with leprosy appears red as fire. It would be interesting to ascertain whether monochromatic light could be used in the same manner as a means of recognising any of our European diseases.

## To Correspondents.

**A. E. C.**—We first described our method of intensifying with permanganate of potash in the article published two or three weeks ago. It simply consists in immersing the fixed and washed negative in a weak solution of permanganate of potash; strength not important. We have used from 5 to 10 grains per ounce. Condyl's fluid, diluted with two or three times its bulk of water, will answer. 2. The exact strength of a dilute solution of anything depends upon circumstances; from 5 to 10 grains per ounce may be used of sulphide of potassium. In what have you failed in using this substance as an intensifier? It is probable that "collodium" is simply a misprint for collodion.

**W. J. A. G.**—We have generally used a hot alkaline solution for removing varnished films. A hot solution of caustic potash will answer well; but the plates should not remain long in it, but be quickly washed thoroughly with clean water, and dried. You will find a method described in our number for April 9th, p. 179. 2. Either a green or a dark blue curtain may be used for pictures without disadvantage. 3. The way we should proceed with a print which had stuck to the varnish of a negative would be to lay a piece of damp paper on the print until it was thoroughly permeated with moisture, and then endeavour to lift it away. If a thin film of the albumen or paper remained attached to the varnish, which in many cases it might, we should remove it with moisture and gentle friction. We are glad the stereoscopic question became clear to you.

**M. Row.**—The majority of the pictures are very good indeed, and show satisfactory progress. The lighting is, in most cases, good. The best poses are the group of two girls, the reading young lady, and the vignette of a lady in black silk dress. The experiments in forcible effects in lighting are good. 2. The statement that the toning bath made with carbonate of soda and gold should not be used again simply means that, as a rule, the

bath so made becomes inert after being made a few hours. There is no harm in using it as long as it will tone the prints. 3. The gelatino-iron developer is excellent under many circumstances. The question of the wisdom of using organic additions to the developer depends upon circumstances. With some modes of lighting there is a tendency to weak images, in which case the organic addition is an advantage; in others, there is a tendency to excess of vigour, and then organic additions will be avoided. The formula of Mr. Hughes is one of the best for a gelatino-iron developer.

**H. S.**—We will examine the deposit, and report in our next. 2. We cannot refer you to any information on the subject, except what has appeared from time to time in our pages. See article in the present number.

**ALBUMEN.**—The yellow spots in the prints are spots of imperfect fixation,—how caused we cannot with certainty say; probably from air-bubbles forming on the prints whilst in the fixing bath, and so causing imperfect action of the solution.

**MAGNESIUM (India).**—Comparatively little experience is on record as yet as to the use of the magnesium light for photographing dark interiors. Mr. Waldeck's account of his operations in photographing the Mammoth Cave at Kentucky furnishes the best hints. You will find it in our Tenth Volume, p. 567. Several lamps were used there, and these were arranged so as to give a dominant light from one direction, with a minor light arranged so as to illumine slightly the deep shadows left by the chief lights. Unless the interior be very small, one lamp would scarcely be sufficient.

**F. M. YOUNG.**—We returned the prints by post, numbered in the order of superiority of tone. None of them were, however, quite the tone we prefer, and which we have obtained by means of the sulphocyanide toning bath. Probably the negatives are not very vigorous, which may account for a slight lack of brilliancy in the prints. The two pale prints, which you suppose probably had no gold, had in reality, we think, a large proportion, but being deposited slowly upon somewhat feeble images, they acquired the pink or mauve tint which deposits of gold do assume on some occasions. That the sulphocyanide toning bath is a somewhat expensive one is, we think, correct, as a large proportion of gold is consumed in using it.

**H. WORTH.**—We are glad that the matter was satisfactorily solved.

**R. B.**—You will find several articles describing the operation of enamelling photographs with gelatine in our Eighth Volume, and also in our YEAR-BOOK for 1865.

**G. FULLAR.**—We have no doubt that the nitrate of silver to which you refer will answer very well for a negative bath. 2. We have no reason to believe that any process vendes as you describe will contain a secret worth the money, but of course we cannot with certainty say whether it is worth the money or not. You will find an article in the present number on the subject. 3. The fault of the print appears to arise from a defective piece of paper, but we cannot say the cause of the defect. 4. We believe that the lens you name is worth its price, and we should select it for the purpose.

**R. M.**—The report to which you refer was full of mistakes, misstatement, and misrepresentation, but was not of sufficient importance for notice.

**L. D. F.**—The collodion appears to have been unsuitable for transferring; much of success depends upon the use of a tough collodion of good body. See article in the present number. Your tone is capital.

**B. A. G.**—You do not describe the toning bath you use; we cannot, therefore, tell you the reason of the bleaching. You state that the bleaching took place after adding chalk to it. If the prints are immersed in a toning bath immediately after making or neutralizing, bleaching will generally take place. Are you sure that you did not leave considerable excess of acid in the chloride of gold you made? 2. The nitrate of copper may be got rid of by fusing the nitrate of silver, and maintaining the heat sufficiently high to decompose the copper salt; but we do not think the presence of a little nitrate of copper at all injurious. 3. The orthoscopic lens is correctly arranged.

**ERRATUM.**—A printer's error occurs in the last line but one of "Echoes of the Month" in our last. For "matters not within their control," read "matters more within their control."

### A MODIFICATION IN TRANSFERRING CARBON AND OTHER TISSUES.

WE have recently had our attention called by Mr. William Firling, an ingenious and persevering amateur of Dorchester, to a valuable modification he has made in the mode of transferring the film containing the image in producing photo-enamels, carbon prints, &c., at once eliminating several difficulties, and securing ease, simplicity, and certainty in the operation.

In M. Joubert's, or any similar enamel process, in which a film of collodion is used to transport the layer of vitreous colour and organic matter, which form the picture, from the flat glass upon which it was originally produced to the surface upon which it has to be burnt, one of the difficulties consists in getting rid of the collodion before burning. It is often found to resist the solvent action of ether and alcohol, remaining obstinately insoluble. Mr. Firling's method gets rid of all difficulty on this score. In his method of enamelling he prepares a tissue resembling carbon tissue, but containing vitreous colours instead of Indian ink or lampblack. This is exposed under a negative, as in carbon printing, with the prepared side in contact with the negative. After exposure the prepared side is coated with a solution of bees'-wax in turpentine, one ounce of the former in three of the latter. When this is dry it is coated with collodion, and then the tissue is placed in warm water and developed in the same manner as a carbon print. When this is done it is placed upon the enamel tablet, or other surface upon which it is intended to be burnt, to which it is made to adhere by means of gelatine. The elasticity of the collodion allows it to be adapted to convex or concave surfaces without wrinkles, and when it is dry it is only necessary to get rid of the collodion to make the picture ready for firing. The tablet is slightly warmed, which softens the wax between the collodion and the image, and on lifting the edge of the collodion film it can be removed without the slightest trouble, bringing with it the coating of wax, and leaving only the image on the tablet.

Mr. Firling adopts a similar plan in carbon printing. After exposing the carbon tissue it is treated with the solution of wax before mounting on the paper with caoutchouc for the purpose of developing. The various manipulations having been completed, and the developed image mounted on its final resting place, instead of sponging the caoutchouc-coated paper with benzole to soften the india-rubber, the mounted print is very slightly warmed, which permits the paper upon which it was developed to be removed at once, taking the wax with it, and leaving the print perfectly clean.

Some examples of photo-enamels and of carbon prints transferred to ground glass and to opal glass, which Mr.

Firling showed us, illustrated the value of this mode of working, the results being in all cases excellent, and the operation, as Mr. Firling assured us, simple and certain.

### MR. McLACHLAN'S DISCOVERY.

MR. McLACHLAN's written and detailed account of his mode of working, brought before the Photographic Society on Tuesday night, does not differ in any material degree from the hasty verbal statement made at the former meeting. After listening carefully to his fullest explanation, we repeat the statement we made a month ago: *assuming the facts to be true, and holding him responsible for their truth*, the communication he has made is a most important, as well as a most extraordinary one. The facts, however, are not easy to verify, as he now states that for a fair trial of the experiment the silver solution must be exposed to sunlight for three months of the most actinic season of the year. As for the only attempts at verification hitherto made, those of Mr. Spiller, they scarcely support the statement made by Mr. McLachlan, who, however, objects both to the experiments and the account of them.

Until we publish the paper in our next it would be obviously unfair to the reader to enter into more detailed comment than we have already made upon his proposed mode of operations. As, however, we give Mr. McLachlan credit for perfect honesty as well as great enthusiasm, we shall not hesitate to comment with equal honesty upon his statements. The especial end he desires is investigation. Experimental investigation will require, he says, three months; examination of the nature of his claims may be made at once. Mr. McLachlan has a right to expect that this shall be done in a fair and courteous spirit, without the ready jibe—so ready on some lips—and the "mockery which is the fume of little hearts." Candid and courteous criticism is the compliment fairly earned by the outspoken liberality with which Mr. McLachlan has made his communication, and in our next we shall have a few remarks to make on the assumptions on which his paper is based.

It is only necessary at present to correct an error in our statement of Mr. McLachlan's formula a month ago. We then stated that to 16 ounces of a 12-grain iron solution  $3\frac{1}{2}$  ounces of acetic acid were added; and this led to the idea in the minds of some that the neutral or alkaline conditions of bath and collodion were corrected by the use of excess of acid in the developer. Mr. McLachlan, in giving his verbal statement of formula at the meeting, said  $3\frac{1}{2}$  drachms of acetic acid were added; but in a subsequent conversation, in which we asked him to verify the short-hand notes of his remarks, he gave the formula as  $3\frac{1}{2}$  ounces, which was incorrect, and, as he now states, must have been a *lapsus lingue* in the excitement of the moment. As experiment

with the developer is impossible until after the lapse of the months necessary to prepare a bath, no inconvenience can have arisen from the error.

### COLLODION NEGATIVES WITHOUT GLASS.

In a recent notice of M. Marion's transparent tissue we referred to Mr. Woodbury's experiments in a similar direction, with a view to provide a light support for dry collodion negatives. We have recently received from him some interesting results illustrating the extent to which he has already worked his project out. These consist of negatives on a support of tough, transparent, flexible collodion, and sensitive plates ready for exposure on a similar support. The support is not too thin to permit easy and safe manipulation with the negatives, or to risk cockling or forming creases; but is, nevertheless, sufficiently thin to permit either side of the negative to be placed in contact with a sensitive surface without loss of sharpness.

The mode of preparing the dry-plate films is very simple. It consists in applying to a plate of glass a coating of castor oil collodion; when this is dry, applying a very dilute solution of india-rubber to protect the first collodion film from being dissolved, when a second is applied. The second coating of collodion is a sample suitable for the dry plate required. This is applied on the india-rubber coating, and excited, washed, treated with a preservative, &c., in the manner usual with the dry process which may be selected. When the prepared film is dry it is cut round the edges, lifted from the plate, and stored in the dark for subsequent use. It will be seen that it will be easy to prepare such sensitive films in large sheets, which may be cut up subsequently to any size which may be required. We believe that Mr. Woodbury contemplates the commercial preparation of such sensitive films; but he has promised, in any case, to supply more precise details of his operations for the benefit of our readers.

### IRON DEVELOPMENT FOR GUM PLATES.\*

BY RUSSELL MANNERS GORDON.

As some of your readers may perhaps be working gum plates, I recommend them, in preference to an alkaline developer, the following iron one:—

Gelatine	...	...	...	1 grain
Acetic acid	...	...	...	15 minims
Iron	...	...	...	20 to 30 grains
Water	...	...	...	1 ounce.

It is perhaps a good plan to dissolve the gelatine in the acid and a part of the water, and the iron in remaining portion, adding them together after complete solution. A gentle heat may be necessary to get the gelatine to dissolve.

After wetting the plate previous to the development (with distilled water), take as much of the above iron solution as may be found necessary to cover it; and add to each drachm one drop of a 30-grain solution of nitrate of silver. Add the silver to the iron *before* pouring it over the film. The development is nearly as rapid as that of a wet plate.

After the details are out, a few more drops of silver may be added to the iron, and this, again and again, poured over the plate to complete the primary development.

When all is out, the necessary intensity may easily and quickly be obtained by the usual solution of—

Pyro...	...	...	...	2 grains
Citric	...	...	...	2 "
Water	...	...	...	1 ounce

And a few drops of the silver solution.

I do not approve of iron development for dry plates in general; but with these gum plates it seems to answer better than anything else.

\* We have recently seen some of Mr. Gordon's negatives, which leave nothing to be desired in technical beauty. In point of sensitiveness, the plates equal, or exceed, any dry plates we know. We shall have more to say on the process in our next. —Ed.

The advantages in this way of working are:—

- 1st. Better adhesion of the film.
- 2nd. Much less blurring.
- 3rd. The appearance of the finished negative is very much like that of a good wet one; there is therefore no difficulty in judging of the correct amount of intensity.
- 4th. The exposure is, if anything, shorter than with alkaline pyro, &c.

It is curious that when using a gelatino-iron developer, the deposit of silver on the film is not removable by friction, while with an ordinary iron solution containing no gelatine it may be entirely rubbed off. And, again, although gelatine certainly necessitates a longer exposure in the wet process when used in the above quantity, it does not seem to do so in the least with these plates.

In preparing gum plates the gum and gallic acid might, of course, be mixed together before applying them to the film; but I found that a solution containing 20 grains of gum and 3 of gallic acid to the ounce of water darkened to the colour of brown sherry in about an hour, and I fancy that a white preservative is less likely to affect the exposure than one of so non-actinic a colour.

### PICTORIAL EFFECT IN PHOTOGRAPHY;

BEING LESSONS IN

COMPOSITION AND CHIAROSCURA FOR PHOTOGRAPHERS.

BY H. P. ROBINSON.

CHAPTER XVI.

"Another important means of expressing unity is to make some kind of sympathy among the different objects, and perhaps the pleasantest, because most surprising, kind of sympathy, is when one group imitates or repeats another; not in the way of balance or symmetry, but subordinately, like a far-away and broken echo of it."—*Ruskin*.

"As men are not to mistake the causes of these operations, so much less are they to mistake the fact or effect, and rashly to take that for done which is not done."—*Bacon's Natural History*.

"Unhappy man! to break the pious laws

Of nature

Howe'er the doubtful fact is understood."—*Dryden*.

"In things the fitness whereof is not of itself apparent, nor easy to be made sufficiently manifest unto all, the judgment of antiquity, concerning with that which is received, may induce them to think it not unfit."—*Hooker*.

VARIETY AND REPETITION (*continued*).—FITNESS.

This law of repetition will be found to pervade all great pictures, perhaps more notably in colour, but also, to a great extent, in the disposition of lines and light and shade. The repetition of incident is almost invaluable in telling a story, of which both Wilkie and Hogarth were great masters. In Wilkie's picture of the First Ear-ring, now in the gallery at South Kensington, in which a woman is performing an act more worthy a savage community than a civilized nation—that is, boring a hole in a child's ear, that jewellery may be hung in the flesh, under a mistaken notion of ornamentation—the action is repeated, or at least alluded to, by the spaniel on the ground scratching his ear with his paw; and in the first of the series of Hogarth's great pictorial epic now in the National Gallery, the Marriage à la Mode, the indifference of the intended bride and bridegroom, who turn their heads away from each other, is repeated in the two dogs at their feet, linked together, but of different minds. The way in which Hogarth made insignificant objects perform a double purpose, and help to tell the story, is simply wonderful. Instances must occur to all admirers of his works, and may be imitated by photographers. In Leslie's "Handbook" many instances are cited; the following, referring to two of the best known works, I quote:—"In the marriage scene in his 'Rake's Progress,' in which the hero, having dissipated his patrimony, appears at the altar with an ancient heiress, we are shown the interior of Old Marylebone Church, at that time standing in an out-of-the-way part of the suburbs, and, therefore, resorted to for stolen marriages, or marriages of which either of the parties had any reason to be ashamed. The church, a very small one, is in a neglected condition, and cracks in the walls, mildew, and cobwebs, would occur to an ordinary painter; but Hogarth has shown a fracture running through the table of the Commandments; the Creed

is defaced by damp; and he has placed a cobweb over the opening in the charity-box. Again, an empty phial, labelled "laudanum," lies at the feet of the expiring viscountess, in the last scene of the 'Marriage à la Mode;' but this was not enough,—he has placed close to it the "last dying speech of Councillor Silver-Tongue," suggesting that it was the death of her lover, and not her husband, that caused her to swallow poison."

Laws become hurtful when they are carried to excess, and repetition becomes caricature when observed so closely as to verge on mockery. There is a curious instance of this in one of Turner's etchings, reproduced by Ruskin, and commended in his "Elements of Drawing." In the foreground, standing on a bridge, are a man, a boy, and a dog; and in the distance, at the top of a hill, are a man, a boy, and a dog, the boy and dog in exactly the same position as in the foreground. This is an example of repetition and symmetry which should not be repeated, and with which it is impossible to sympathise. In the same book Ruskin mentions a picture by Vandyke, exhibited at Manchester, in 1857, representing three children in court dresses of rich black and red. The law of repetition was amusingly illustrated in the lower corner of the picture by the introduction of two crows, in a similar colour of court dress, having jet black feathers and bright red beaks.

The true end of variety is to give relief to the eye; repetition is harmony until it becomes monotony; then variety should step in to relieve the tired and perplexed attention. Deviation from uniformity in the outlines of nature gives greater zest to the pleasure arising from the contemplation of order and regularity. Alison, in his essay on "Taste," observes, "Beautiful forms must necessarily be composed both of uniformity and variety; and this union will be perfect when the proportion of uniformity does not encroach upon the beauty of embellishment, and the proportion of variety does not encroach upon the beauty of unity." Which sentence, properly understood, contains the essence of the art of composition.

Repetition is one of the principal elements of repose in art. No picture can be considered to have attained any approach to completeness that has not repose, and, for many reasons, it is still more necessary in photography than in any other means of representing nature. I am not certain that any perfect photograph—that is, one that has produced a perfect sense of completeness in the beholder—has ever been done which has not this quality to a very great extent. In the "Blind Fiddler," the expression and use of repose is perfect. The relief given by the happy serenity of the old man and the fiddler's wife and children is a very agreeable contrast to the action of the man snapping his fingers and the boy with his improvised musical instruments. I am aware that very exquisite large pictures of waves in motion have been published by Le Gray and others. I also know that Blanchard, Breese, Wilson, and one or two more, have attained very great success in representing moving objects in pictures for the stereoscope; but, even in its highest flights, art can only suggest motion, and those artists who try to represent it appear to me to be nearly guilty of a solecism. The pictorial representation of a moving mass depicts as immovable that which is in motion. The representation is therefore false. This is, perhaps, allowable in painting, where a certain license is not considered improper; but for the photographer to do so is entering upon doubtful ground, and requires grave consideration. To represent the result of motion would be legitimate. It is a rule in sculpture that the right moment for representation is that of *arrested* or *suspended* action. If photographers would also observe this rule it would save their works from the risk of any appearance of extravagance, or any suggestion that they represented a doubtful truth.

The last paragraph suggests that a word or two on what is fit to represent by our art may not be out of place here.

The proper adaptation of means to an end—or, in other words, "fitness"—is a great source of beauty. Not only is fitness the proper application of means, but—especially in our

art—the production must be a fit result of the means employed to produce it. Photographs of what it is evident to our senses cannot visibly exist should never be attempted. The absurdity of representing a group of cherubs floating in the air, for instance, is felt at once. It would be possible, by double printing, to make a very passable photograph of a centaur or a mermaid, but the photographer would discredit his art; he would not be believed, and would deserve to be set down amongst charlatans and Barnums. He would be worse than the great showman, who, to his credit, confessed himself a humbug, while the photographer would expect the world to believe his work to be a truth. I am far from saying that a photograph must be an actual, literal, and absolute *fact*; that would be to deny all I have written; but it must represent *truth*. Truth and fact are not only two words, but, in art at least, they represent two things. A fact is anything done, or that exists—a reality. Truth is *conformity* to fact or reality—absence of falsehood. So that truth in art may exist without an absolute observance of facts.

A great part of the emotion of beauty which we feel in regarding nearly all manufactured articles that aspire to this quality has its origin in fitness. Decorative beauty depends, in a great measure, on fitness, and the beauty of proportion is also to be ascribed to this cause. Objects which are disgusting in themselves may become beautiful to the eye which sees their usefulness or fitness. For instance, we hear the surgeon talk of a "beautiful preparation," or a beautiful instrument.

It is no fault in a photographer that his art will not carry him as far as paints and brushes do the painter. His productions would only be defective when he failed to do what was possible in his art—an art in some respects more difficult than that of the painter, because, like sculpture, more circumscribed and limited. The photographer must not let his invention tempt him to represent, by any trick, any scene that does not occur in nature; if he does, he does violence to his art, because it is known that his finished result represents some object or thing that has existed for a space of time before his camera. But any "dodge, trick, or conjuration" of any kind is open to the photographer's use, so that it belongs to his art, and is not false to nature. If the dodges, tricks, &c., lead the photographer astray, so much the worse for him; if they do not assist him to represent nature, he is not fit to use them. It is not the fault of the dodges, it is the fault of the bungler.

To conclude this subject, the painter may imagine new worlds, and interpret his imagination with his pencil; he may paint an embodiment of that which has not yet occurred, such as the last judgment, for example; he may represent angels and cherubim, and he does not commit a very great mistake, or at least one that has not already been condoned by artistic opinion. But, on the contrary, if the photographer, who could, if he had the skill, with the means at his disposal, follow very closely after the painter in representing his ideas of things unseen, attempts to do so, he holds his art up to ridicule and contempt; the reason being that he violates "fitness."

#### COPYRIGHT AND PIRACY.

[THE following article is from the pen of a gentleman whose experience in connection with the production and publication of engravings as well as photography entitles his opinion to much weight. We have always endeavoured, whilst giving the strongest condemnation to piracy, to deal fairly and honestly with both sides of the question. In doing this our contributor seems to think that we and some other portions of the press have scarcely done the print publishers justice. We willingly, therefore, give prominence to his views.—Ed.]

Although much has already been written on this subject, the question still remains apparently as obscure as ever. Not

a little of this unsatisfactory state of things is mainly attributable to the misdirection given, unintentionally, no doubt, by some of the writers who have attempted to clear the way without sufficiently studying the question at issue.

The first point to be determined seems to be whether that portion of any artistic property called "copyright" shall be set apart as being an exceptional kind of property, falling under an exceptional rule. A man may enjoy the undisturbed possession of any sort of property acquired legally, and for a legitimate purpose, but it appears that such is not to be expected in the case of the copyright works of art. The Act 25 and 26 Vic. has recognized a property in works of art, designated under the name of "Artistic Copyright," and has regulated the legal transmission of that property from the creator or owner of it into other hands, but it has hitherto utterly failed in securing to the purchaser of that particular property the lawful advantages he had a right to expect from his purchase. A publisher of books is willing to pay to a popular author a considerable sum of money for the right to publish the manuscript so acquired by means of the press, secured, as he thinks himself, by the existing laws against any infringement of his property; but, assuming for a moment that means were to be found to reprint a book as cheaply and as rapidly as an engraving can be reproduced by means of photography, could any one pretend to palliate the offence on the plea that such a book being only obtainable at a high price, it was scarcely wrong to endeavour to satisfy the demand of thousands of persons by placing within their reach a spurious copy of the original book made in defiance of the law, and circulated to the great detriment of the publisher?

The pretence of the generality of offenders, that they acted in ignorance, not being aware that the work they copied was "copyright," is totally inadmissible; it is a dishonest speculation, entered into deliberately, with the avowed object of securing a large trade with the many who would not purchase the original engraving on account of its high price, and who choose to shut their eyes to the fact that they are buying *stolen goods*. The very mode of circulating and disposing of those pirated copies is sufficiently suspicious to awake in the minds of honest people a notion that there is something wrong; they are not sold in open daylight, but, in general, are kept in a back part of the shop, and only brought out when the vendor thinks he can rely upon his customer; or else a hawker of these photographs comes into the office of a gentleman just at dusk, or near closing hours, and begins to exhibit other works before he produces these piracies, generally succeeding in persuading people to purchase, but never leaving his address, as a rule.

The "moral wrong" of which printsellers are accused in the article reprinted from a contemporary is simply ridiculous; and it is a novel idea that a tradesman is bound to carry on business for the advantage of others, and to his own detriment; that he ought to lay out large sums of money to procure enjoyment to thousands of the art-loving public, and take his chance of any remuneration as well as he can, not as he considers it safe to himself. It would, no doubt, be very desirable if the productions of our modern artists (for those are chiefly the subjects chosen for piracies) could be placed within reach of the many; and if a picture itself could give a good reproduction by means of photography, there might perhaps be found some artists willing to enter into combination with a photographer, as suggested by the article alluded to, with a view of publishing their works; but the practice has shown that, except in a very few cases, photographs executed direct from the picture were found to be very unsatisfactory, and the really fine photographs executed or circulated by the pirates are all done from excellent engravings which have cost a publisher large sums of money. This is a point of considerable importance in the discussion of the subject. When the time comes for a legitimate return of his outlay, in steps the photographic pirate, who perpetrates a double injury: firstly, on the publisher, who is fraudulently deprived of the profit to which he was entitled

by a cheap reproduction of the engraving circulated extensively in competition with the print; and also by robbing the engraver of the merit which attaches to a successful engraving, since his name does not appear in any way on the photograph copied from it. It is inconceivable that many enlightened writers—the editor of the *Athenæum* amongst others—should allow themselves to be carried away from the main point through the liberality of their minds; and the proverb, "We must be just before we are generous," might be applied to them.

The argument of the difficulty in ascertaining which are or are not copyright in works of art cannot be maintained, for no one can seriously pretend that a man picking up a purse containing money has a right to appropriate the contents to his own use under the plea that he does not know to whom it belongs, and does not choose to make inquiries. But in most, if not all, the piracy cases that have come before the Courts, the photographer must have known the name of the publisher whose property he was dealing with from the engraving itself, as it was engraved in the plate, as well as the address, and no possible excuse can exist in extenuation of the dishonesty practised.

Printsellers are also criticised upon their mode of conducting their business, and especially for selling an unlimited number of so-called proof impressions at an exorbitant price; they are advised to discontinue the practice, and to sell only prints at a moderate charge, being assured that their interests, as well as those of the public, will be benefitted by a considerably increased sale. It is difficult to say that a man who has had many years' experience of his business knows not in what direction his chance of success lies, and that he ought to be guided by those who know nothing about his trade, except from theory or sentiment. The abuse which is well known to have been practised in the sale of *proofs*, especially those termed "artist's proofs," cannot be too strongly reprobated, and if any mode could be adopted to do away with the system of having so many classes of proofs it would be as well; but there will always be amateurs ready to pay an advanced price to secure an article of comparative scarcity, and the origin of the system is simply this: in former times an engraver was allowed to retain a limited number of impressions from his finished plate before delivering it up to the publisher for publication; this number varied from six to eight, rarely exceeding ten: these proofs bore no other name or signature but the name of the engraver, scratched in the plate with an etching point by himself. The publisher then had the margins well cleaned, and his name and address engraved in small letters, and no title yet; and the impressions, limited in number in *those days*, were sold as "proofs before letters," to distinguish them from those that were subsequently printed after the title and designation of the subject had been engraved at the foot of the plate. It so happened that some amateurs became aware of the existence of a state of the plate antecedent to that which they had purchased as the first-class proofs, and they were anxious to obtain the proofs kept by the engraver, as being the very best of all, and to which the name of the artist's proofs was given. The publishers soon found out they could realise a good profit from the sale of such proofs at a high price, and they had some printed off, firstly in moderation, and gradually increasing in number as the demand for them extended, until, in a memorable case of a highly successful engraving from a modern English artist, the publisher had so many artist's proofs struck off (a *limited number only* to be published, so ran the prospectus issued) that the copper plate had actually to be repaired before the *prints* began to be printed.

The quotation in the article above alluded to of a well known historical engraver, that "it was customary for the engraver to receive two-thirds of all proof impressions actually printed before the delivery of the plate, is obviously an error, and no publisher in his senses could subscribe to such a condition; in all cases the number is limited before-

hand in the written agreement between the parties, and six to ten is the usual number allowed.

In concluding, it is necessary to endeavour to refute an opinion put forward, no doubt in sincerity, but equally erroneous, that the sale of a valuable engraving could be enhanced by the publication, simultaneously, of a photograph of a reduced size and price. The contrary has been proved to be the result, and those publishers on the Continent who have resorted to the recent practice of having some of their fine engravings photographed and published by themselves, have only done so after they had exhausted their chance of selling the engravings on their merit.

Many plans have been suggested, but only one would be likely to abate, perhaps to cure, the evil; this would be, the introduction in the amended law on artistic copyright, to be brought before Parliament, of a stringent clause making it compulsory for any photograph, large or small, not to be allowed to be sold or to circulate except with the name and address of either the producer or the publisher thereof, and a heavy, not a nominal penalty, easily recoverable, for any and every copy found contravening, besides confiscation. By such means only can the dishonest practice be combated, and there will no longer be a difficulty of punishing the real culprit; any one found dealing with anonymous photographs must do it at his peril, and amateurs' productions can never come into the market as such, and without bearing any designation, under pain of being seized and destroyed, besides the penalty incurred for each offence.

#### ON SOME OF THE CHANGES WHICH TAKE PLACE IN PHOTOGRAPHIC MATERIALS AND CHEMICALS AFTER A LENGTHENED DISUSE.

BY JOHN BOCKETT.\*

HAVING done comparatively very little in photography for a period extending over nearly two years, I was surprised the other day, upon having my glass house and laboratory thoroughly cleaned out and put in order, at noticing the ravages that time alone had made with the materials and chemicals contained therein. Although in all probability this short communication may not contain anything that is new, but, in fact, really easy of explanation, still, sometimes, out of a great deal of rubbish some one grain of novelty may be extracted.

The first matter on hand was repapering the window of the photographic dark room, and for this purpose I have always used an orange-coloured paper, two thicknesses of which were simply gummed to the inside of the window-frame (the plan of using chrome yellow on the glass being very good, but, to those who practise photography purely as amateurs, and who will some day or other have to leave their residence, not an easy thing to get off when once on). To resume: upon stripping the old paper away, that nearest the window had become completely bleached, and, what was more extraordinary, had become so completely decomposed as absolutely to fall to powder. I am, of course, aware of the bleaching power of the sun, and that in all probability the colouring matter of the paper had been turmeric, but the extreme rottenness is not so easily explained. With regard to the article which accumulates everywhere—I mean dust—there was no lack, and a very curious conglomeration it is; so much so that the circumstances under which it is deposited, as also its composition, in all probability, will form the subject of a short paper at one of the microscopical societies to which I have the honour to belong, and to which it is more referable than to a photographic society.

Before commencing any attempt at negative taking, it behoved me, as every photographer will suppose, to go through a proper amount of filtering; and I feel sincerely obliged to Mr. Hart for his filtering apparatus, which at once operated after having had the negative bath

solution standing in it undisturbed for so long a period. But even with this apparatus something was to be learnt. The powdered glass and felt was all right, but the India-rubber tubing was anything but up to the mark. Mind me, I find no direct fault with it, as, for the time being, the tube acted as it should do; but the nature of the rubber is most undoubtedly changed. It is now no longer the supple, pliable article it once was, but is rigid, and retains the form of coil in which it was placed when the bath was set aside.

My next examination was of the bath after filtration. I always have used (and consequently this one was) a decidedly acid bath; but, to my great surprise, the solution was very alkaline; so much so that exceedingly red litmus paper rapidly assumed its blue colour. As we all know that glass in a state of division is partially soluble, may that have had anything to do with the matter? At all events, when acidified with a drop or two (I think about five minims), the bath for stereo-plates gave as clean negatives as possible.

A word now on our next article—pyrogallic acid. The bottle containing this substance, and devoted thereto for the last ten years, has gradually attained a brown deposit, which tenaciously adheres to the side, and preserves the fresh pyro. put therein. The dry pyro. was as good as ever, but wherever the acid had been mixed, either with citric or glacial acetic acid, decomposition had set in, and, even when mixed with pure alcohol, had become as black as ink. Another fact also cropped up with the citric acid: clots of mould had formed, and would render the solution perfectly useless; but with the glacial acetic acid this did not appear to have taken place. I regret now I did not filter each, so as to ascertain, in spite of the objectionable colour, whether any reducing power was still left.

We next arrive at collodion. That which I have always used has been Mawson's, and I think I have some that must be nearly as old as the firm who made it; but I contend that every practical photographer should know to a day the age of his collodion. This idea struck me almost as soon as I began to practise photography, and I used to stamp out with a gun punch discs of gummed paper, which I attached to my collodion bottles; but this involved some little trouble and, I fear, sometimes was omitted altogether. An improvement upon this plan was to make the top of the collodion bottle-cap rough, and then with a lead pencil write the date of mixing, thus:—9-4-67, &c. It so happened that the purpose for which I wanted it was for copying, and, although slow, still it worked very clean; but, for portraiture, the whole of the half shadows were gone. Even the old collodion possessed considerable vitality.

With regard to my fixing agents: the cyanide of potassium had deliquesced in the stoppered bottle, but in solution remained as powerful as ever, while the hyposulphite of soda remained perfectly good, although the crystals were kept in a loosely-stoppered jar; also in solution it was as good as ever.

The foregoing gets us through our negatives, but still we have the vicissitudes of printing. The paper I always use is the ordinary albuminized Saxe, and, although we all as a rule like freshly-prepared paper, I am bound to say that this worked as well as if purchased only the day before. The silver bath, prior to using, was, of course, filtered, and I was surprised to find the heavy deposit of black (I presume) oxide of silver; but still the solution sensitized the paper as well as could be.

With respect to the chloride of gold: my practice always was, and would be, the moment a capsule was broken, to convert it into a solution of one grain to the drachm of water; and this I found was perfectly unaltered.

The toning bath which I use is that prepared with chloride of lime described long ago; and although I could hardly hope an old toning bath would act satisfactorily, still, by adding to the 20 ounces which remained about 2 drachms of the solution of chloride of gold, all went as well as if kept at a proper age on purpose. Even the old solution of

\* Read at a meeting of the North London Photographic Association, May 11, 1868.

hypo acted well, the smell of the muriate of ammonia which I used always to add being still apparent.

But though this virtually solved all doubts as to the present condition of my chemicals with regard to taking a negative and printing therefrom, there remained a few which I had a look over. Protosulphate of iron, phosphate of soda, bichloride of mercury, were unaltered; but sulphocyanide of ammonia had become red and partially dissolved; citric acid pink, although kept entirely in the dark. The neck of the nitric acid bottle, curious to say, had got a crop of acicular crystals around its neck, and solution of uranium had assumed a most splendid purple; in fact, as a friend of mine said, the very thing for a chemist's show bottle.

Another curious fact was that two or three books of litmus paper had become quite pink, and, although I restored them by means of liquor ammonia, in forty-eight hours they had again gone back to redness. This would almost show that either the bath gave off its acidity, which was alluded to in a former part of this paper, or that the atmosphere had become acid by some other means.

I am very glad to be able to say that, with regard to my lenses, the oxidation complained of by many persons has not attacked any of mine, one or other of them having been made by the firm of either Ross, Dallmeyer, or Grubb.

With regard to residues: I formerly emptied all my washing from printing into an old oil jar, with an American tap inserted about one-third of the way up the jar, adding common salt to throw down the chloride; but the glaze apparently was not strong enough to retain the solution, and the whole of the fluid has percolated through the jar, and simply left the white deposit.

Finally: I lighted upon some old gutta-percha; and if, as it really is, that I have ever had a dislike to this substance for any photographic purpose at all, it was considerably strengthened by the appearance of this substance. Originally a dipper made out of pure gutta-percha, and to my own knowledge possessing considerable elasticity, it has become as dry and rotten as a very rotten stick, and seems to have lost all its former characteristics.

I feel much obliged to you for allowing me to absorb your time; but out of the foregoing I hope some discussion will arise, the more so as I think the decay of the yellow paper wants explanation; also the action of nitrate of silver upon pure india-rubber; the fact of an acid bath becoming alkaline, and whether the powdered glass has anything to do with it; whether other photographers have also found that collodion will, in connection with cadmium, keep a certain amount of sensitiveness indefinitely; that the atmosphere of dark rooms has a tendency to becoming, and that our own English objectives have not a tendency to become, dull by oxidation; and, lastly, that some salts will keep indefinitely when dissolved, and that others will not keep at all when kept in solution.

#### REDEVELOPMENT BY NITRATE OF SILVER AND CITRIC ACID.

BY JOHN C. BROWNE.\*

A few days ago, in looking over some negatives taken during 1864 and 1865, I was surprised to find that a very decided change had taken place, which rendered a number of them almost useless.

The majority, at the time they were taken, were passably fair negatives, of good printing strength; but now many of them are so intense that prints made from them must necessarily be hard and chalky.

At the time these pictures were made I regret to say that I, like many others, was disposed to make negatives entirely too strong, losing thereby much softness and half-tone in the finished prints.

To accomplish this result, many of my negatives were redeveloped with nitrate of silver and citric acid, made in this manner, i. e.:-

Water	...	...	...	1 ounce
Citric acid	...	...	...	30 grains
Nitrate of silver	...	...	...	20 "

After developing with iron, wash well, and pour a small portion of this solution over the plate, drain off the excess into a different bottle, and redevelop with iron. My boxes, containing a number of negatives known to have been redeveloped by this process, were examined, and, after careful comparison with others taken about the same time, which were in good condition, no redevelopment being necessary, I was for some time at a loss for the probable reason, and can assign no other cause for the changed appearance of these negatives than the use of citric acid in the manner described.

Those negatives in which the greatest change was noticed had been twice redeveloped, using the silver and citric acid solution each time, but well washed both between and after the operations.

Viewed under a microscope, a great difference was observed in the deposit of silver upon the plates in comparison with negatives taken at a much later date, although redeveloped by the same method.

Collodion used in 1864-65:-

Iodide of ammonium	...	...	5 grains
Bromide of potassium	...	...	2 "

Bath and developer as usual; fixed with hypo, well washed, and varnished with Anthony's flint varnish.

I was greatly in favour of this plan for adding strength to the negative. The process was under perfect control, and when care was exercised the results were uniformly good; but the present difficulty has somewhat shaken my faith in what I have considered one of my most valuable formulæ.

In several cases I have seen negatives from which large numbers of prints had been made rendered very intense from absorption of silver from the sensitive paper; but that cannot be the cause of this trouble, for very few prints have been made, not over half a dozen from each negative.

#### ON BLURRING, WITH A NEW REMEDY.

BY M. CAREY LEA.\*

My object in the present paper will be to endeavour to show—

1. That the precise manner in which blurring results from internal reflections has not been hitherto explained.
2. That the remedy applied (wet red blotting-paper on wet plates, painting the back of dry ones), has been a very imperfect one.
3. That in the case of dry plates, at least, a much better treatment may be employed, which principle may possibly be extended to wet plates.

Blurring is usually explained as resulting in the manner shown at Fig. 1; that is, that a ray of light, A B, falling upon the outer surface of the sensitized plate, is refracted

through in the direction B C to the back at C (the thickness of the plate is exaggerated to make the action plainer). At C part is transmitted, and escapes out of the posterior surface

\* Read before the Photographic Society of Philadelphia, March 4.

\* Philadelphia Photographer.

If the litmus be used in excessive quantity it may cause a slight granularity of the image. This need never happen, however, and does not when the colouring matter is kept within reasonable limits; in fact, I never saw it happen but once, and then when the experiment of a very large portion of litmus was tried.

It is evident, then, that the use of this new means involves far less trouble than painting the back, at the same time that it is far more effective. To paint the back, the annatto bath must be got into good condition for each batch of plates, and must be applied at the risk of injuring the film with the fingers. The plate cannot be supported in a rack without the risk of sticking fast to what the back rests on. Again, before developing, the colour must be carefully removed with a sponge or wet cloth; whereas, with the new method, the bottle of litmus is prepared with care, and lasts for a long time, and the trouble for each batch of plates is that of pouring a little into the bath once for all; in fact, it is so little as not to be worth reckoning at all.

Although this method was devised expressly for the process which I have lately published, there is no doubt that it is suitable for others, perhaps for all dry processes, especially as the sensibility of the plate (at least in my own process) is enhanced by it. I have not tried it with any but the alkaline development, but there seems no reason that it should not be used with pyro and silver development, and I expect to use it for such.

I take this opportunity of calling attention to a fact that I have lately noticed, that if a developer of carbonate of ammonium be used too strong, it may, instead of continuing the development, exercise a reversed action, and dissolve off the fainter parts of the image. It consequently becomes of great importance, in all alkaline developments, to attend to this. I have seen this action take place with a developer containing about 6 grains of carbonate to the ounce, and as some have advised to use the alkaline solution as strong as 20 grains, it is evident that such a developer must produce harsh pictures by first bringing out great intensity, and then removing the delicate details in the shadows, precisely what it is most desirable to preserve. Whether the 20-grain formula was a mistake or misprint for 2 grains, I do not know; but this much is certain, that the quantity of carbonate of ammonia in the alkaline developer should, at the commencement of the development, not exceed 1 grain to the ounce, and this may be raised to 2 or 2½, but should not exceed the latter quantity if the best results are desired.

#### MR. CHANCE'S LECTURE ON THE MANUFACTURE OF GLASS.

In his lecture before the Chemical Society, Mr. Chance, of Birmingham, whose name is associated with the finest glass in the world, gave a comprehensive description of its manufacture generally. He stated that the American sand is considered the finest of all; then that from Fontainebleau; Belgian next; and, of English samples tolerably free from iron, the deposits occurring at Leighton Buzzard were in great demand, this quality, though of a yellowish tint, containing less iron than many whiter samples. With respect to the alkaline ingredients for glass making, the substitution of the sulphate for the carbonate of soda—due to Gehlen—tended to cheapen the glass, but at the sacrifice of quality. For the best kinds of plate glass the carbonate (soda ash) is always employed. For the common blown window glass the sulphate answers well: it will permit the use of larger charges of lime, and the glass produced from it is harder, takes a better polish, is less liable to devitrification, and to the alteration of its surface by what is termed "sweating." The addition of carbon in the form of charcoal, or powdered anthracite, facilitates the reduction of the sulphate, and tends to promote vitrification. Only one atom of carbon is, in practice, found sufficient for two atoms of sulphate of soda. The object of its employment would, then, seem to consist in furnishing the means of reduction of a part only of the alkaline sulphate to the state of sulphite, and not to sulphide. Glass made from sulphate of soda is of a bluish, whilst that made

from the carbonate is of a yellowish tint. When an extra pale colour is desired, the carbon is kept at a minimum.

The average composition of different qualities of glass was stated to be as follows:—

#### Crown and Sheet Glass.

					English.	Foreign.
Silica	...	...	...	...	73	74
Lime	...	...	...	...	13	14
Soda	...	...	...	...	13	11
Alumina, oxides of iron and manganese	...	...	...	...	1	1
					100	100

#### Ancient Glass.

					12th century.	16th century.
Silica	...	...	...	...	51.60	54.60
Alumina	...	...	...	...	2.16	8.96
Protoxide of iron	...	...	...	...	1.53	0.75
Lime...	...	...	...	...	8.04	19.31
Magnesia	...	...	...	...	2.22	3.43
Alkalies	...	...	...	...	34.40	12.95
					100.00	100.00

The use of peroxide of manganese and arsenious acid in glass making is mainly for the purpose of effecting the peroxidation of the iron, which, in this state, has far less colouring property. The Belgian manufacturers are said to have discontinued the use of the above metallic oxides. The purest coloured flint glass is composed of sand, potash, and oxide of lead. For some kinds of optical glass a portion of the red lead is replaced by lime, and if the lead is used in excess the heavy flint glass produced has a strong yellowish tint. When much manganese is employed to correct the colour arising from impurities in the glass mixture, there is a tendency for the glass to undergo changes of colour upon exposure to sunlight; and a greenhouse rooted with glass in which manganese has been used will often display after a lapse of time a great variety of tints. After referring to Mr. Gaffield's experiments on the action of sunlight upon glass, and to the practical conclusion arrived at, to the effect that the alteration in colour was solely due to the different states of oxidation of the manganese, the lecturer asserted that he had noticed changes of colour in glass which did not contain a trace of this metallic oxide, and specimens were exhibited in which the glass, originally white, had become strongly tinged with yellow.

#### Proceedings of Societies.

##### NORTH LONDON PHOTOGRAPHIC ASSOCIATION.

The usual monthly meeting was held in Myddelton Hall on the evening of Wednesday, May 6th, Mr. G. WHARTON SIMPSON in the chair.

The minutes of a former meeting were read and confirmed, and Mr. H. Buttrum was elected a member of the Society.

The CHAIRMAN called attention to some fine examples of photography exhibited by Mr. Hill, consisting of flowers the size of nature, by Fredricks, of Berlin. By the use of a concentrated light from one direction, the flowers were made to give cast shadows on the screen to which they were attached, and this, together, with the excellent photography, produced a wonderful effect of relief. The Chairman also called attention to some very fine examples of Mr. Woodbury's process, and to a sample of Marion's transparent pellicle.

Mr. BOCKETT then read a paper on the Changes in Chemicals during lengthened disuse (see p. 233).

A general conversational discussion followed on the various points raised in the paper.

Mr. HILL mentioned an experience with old pyrogallie acid, which, without any change in colour, had the peculiar property of giving a blue kind of deposit all over the negative.

After some general conversation, in which the Chairman pointed out that the deterioration in pyrogallie acid by keeping was generally shown in its discolouration, from having absorbed oxygen, a conversation on the subject of the deterioration in the india-rubber tube followed.

The CHAIRMAN pointed out that india-rubber was really a photographic substance, and was acted upon by light and air, losing its elastic character, and becoming hard, insoluble, and resinous.

Mr. BOCKETT said that the tube he had mentioned had been kept in the dark.

Mr. HART said that immersion in boiling water would, in all probability, restore its pliability and elasticity. He often found that india-rubber got hard with age; but if it were pure—and he only used the pure in his filters—immersion in boiling water, or boiling for a few minutes, restored it.

After some further conversation,

The CHAIRMAN stated that he had kept a sample of collodion which he had made, which contained mixed iodides and bromides of cadmium and sodium, for upwards of three years without deterioration. Mr. England made it a practice to keep a stock in his cellar ripening, preferring to use it at least two years after mixing.

Mr. SMITH said he believed that Mr. Ponting's practice was similar.

A conversation on the acid bath becoming alkaline by standing followed; the only suggestion of a cause being the possible effect of the alkali in the powdered glass in the filter or in the glass vessel.

After some further desultory conversation the proceedings terminated.

#### LONDON PHOTOGRAPHIC SOCIETY.

The usual monthly meeting was held in the Architectural Gallery, Conduit Street, on the evening of Tuesday, May 12th, Mr. J. GLAISIER, F.G.S., in the chair.

The minutes of a previous meeting were read and confirmed, and Mr. E. Ernest Dymond was elected a member of the Society.

Mr. McLACHLAN then proceeded to read a paper stating in fuller detail the mode of working he described at the last meeting. He dwelt on the fact that distinctly different results were obtained by different samples of the nitrate of silver or sulphate of iron employed. Boiling the solution of some samples of the iron salt with a little "alkaline alcohol" was necessary to get the alcohol into "chemical combination" with the water. He considered the use of bromides in the collodion and of nitric acid in the bath decidedly injurious. At the conclusion of his paper (which will appear in our next) he said that he was fully prepared to meet with incredulity. He would not himself have believed similar statements made by other persons. The truth of what he had said could only be tested by experiment, and he was fully prepared to go to the test with any committee which might be appointed.

Mr. SEBASTIAN DAVIS, after some remarks on the interest of the subject, said that he understood Mr. McLachlan to recommend absolutely neutral collodion and bath, and very acid developer. The addition of an alkali on the collodion would, however, in some cases, tend to make it so powdery that the film would not hold the sensitive salts. In regard to the objection to nitric acid he agreed with Mr. McLachlan. He always neutralized any trace of nitric acid present in a new bath, and then added acetic acid. The difficulty which arose as to the developers was, that whilst Mr. McLachlan recommended different kinds of sulphate of iron for different purposes, he left them without information as to the differences in the samples. He proposed that some specimens be placed in the possession of the Society for analysis. He hoped that the enquiry stimulated by Mr. McLachlan's communication would aid in eliminating uncertainties from their practice.

Mr. FRY thought they now had the matter in a nutshell, and they could form a definite opinion of its value. Those who liked a spade called a spade would be pleased with the plain speaking of Mr. McLachlan, and he thought they ought to deal equally plainly with the subject in discussion. He should therefore make one or two remarks on Mr. McLachlan's statement. He had said that the vagaries of the nitrate bath were so perplexing that no experience was sufficient to conquer them. Now was this so? Ten years ago such a statement might have appeared true, as at that time they knew much less than was now known. But were the mass of competent and capable photographers now in that position? He certainly believed not. Mr. McLachlan, it appeared, thought otherwise, and he had given them a remedy which seemed to him most unlikely to aid them, but which they must wait in any case for three months before they could apply. He must confess that as a whole he could not regard the matter favorably. It seemed to him to be utterly wrong to begin with an impure nitrate of silver, and then spend three months in getting rid

of the impurity. He believed there were plenty of pure samples to get. He believed that, as a rule, photographic chemicals were as pure and as honest as any product of any kind sold in the world. The chief difficulties which at any time arose were simply due to want of experience. But the want of experience in individuals must not be taken as an illustration of the condition of photography among competent men. For instance, they had at a recent meeting an interesting statement of the difficulties of an amateur in South Africa, from which they might have been led to believe that Natal was as full of troubles to the photographers as to the ecclesiastical world; but the simple truth was, these difficulties arose from want of experience. In fact, he must say that he agreed with a recent writer\* who said that the error of Mr. McLachlan was that he under-rated the capabilities of photographers. But if some people would make very small baths, and use them much, or would doctor their baths, they ought not to be surprised if at times they were beset with troubles and uncertainties.

Mr. SPILLER said the especial aim of Mr. McLachlan appeared to be to introduce harmonious conditions into the preparations with which he worked. For this aim he gave him all credit; but when he entered into the detail of his propositions he felt somewhat at a loss. When Mr. Foster and himself received the communication upon which they had already reported, they found a difficulty in the fact that Mr. McLachlan frequently used terms in which he gave a new sense to old definitions. For instance, he had talked to-night about alkaline alcohol, whilst chemists knew that alcohol could neither be acid nor alkaline. Then they were, at the outset, at a loss to identify the various salts described, and to the present time he had no idea of what the peculiarity of the nitrate of silver recommended consisted in. Could Mr. McLachlan now show him a sample?

Mr. McLACHLAN handed an unlabelled bottle containing white crystals to Mr. Spiller, who pronounced the contents to be iodide of potassium. The mistake being rectified, and a sample of the nitrate of silver produced and examined,

Mr. SPILLER proceeded: Of course he could not venture to speculate on the nature of the impurity present in the salt at present, but he had been led to believe that it was not improbable that it contained chloride of silver in combinations, and a sample which he now produced contained one per cent. of chloride in combination with the nitrate. In his remaining observations he would read some brief notes of the experiments he had already made:—

Ten days after Mr. McLachlan described his new system of producing negatives in the statement made at the last public meeting of this Society, I published in the PHOTOGRAPHIC NEWS (April 24th) a letter or article entitled "Observations on Mr. McLachlan's Process," in which I suggested the possibility of chlorine taking part in the decomposition said to occur when the nitrate of silver in the form of emulsion solution is exposed to sunlight.

My grounds for believing in the possible occurrence of chlorine were, firstly, the description given of a special quality of nitrate of silver which is sometimes to be met with in the form of "moist and dirty-looking crystals," such as would ordinarily be rejected by photographers, but now is to be preferred. Secondly, that chlorides are amongst the most commonly occurring impurities in water, and are almost invariably contained in commercial qualities of nitric acid; so that in the preparation of nitrate of silver from an inferior acid and the use of anything but the purest description of distilled water, there would be some probability of chloride of silver being intermixed with the nitrate, and forming a combination which is affected by exposure to light.

I have since made direct experiments on this point, and find that chloride of silver is much more soluble in the nitrate than my previous experience led me to anticipate. I exhibit a sample of crystallized nitrate containing one per cent. of chloride of silver in intimate union, if not, indeed, in direct chemical combination. Such a product must always be in the form of small crystals, and, unless special precautions are adopted, would invariably be discoloured by light. I made it by dissolving 1·17 grains of rock salt (pure chlor. of sodium) in a small quantity of water, and adding 340 grains of pure crystallized nitrate of silver. The precipitate at first formed soon became redissolved upon warming and consequent evaporation of the water, the chloride of silver being, to a certain extent, soluble in a strong solution of the nitrate, and apparently having the power of crystallizing with it. A special experiment to decide the extreme limit of solubility of the chloride and a warm saturated solution of the nitrate showed that it was possible to dissolve as much as 4·7 parts of chloride in 100 of the nitrate. A compound containing this high proportion of chloride cannot, however, be manipulated, for on adding a mere trace of water the white curdy precipitate begins to

\* See Echoes of the Month in our issue for May 1st.

appear. The fact of such a combination being established lends support to the opinion I have hazarded respecting the chemical quality of the silver crystals employed by Mr. McLachlan. I do not, however, mean to assert that his black-looking article contains more than a trace of the chloride, but the presence of this body, even in a small amount, must be allowed to have great influence in altering the properties of so delicate a chemical preparation as the nitrate bath.

A few words, finally, with respect to the amount of acid liberated in the trials by which the success of Mr. McLachlan's expedient was in my hands established. I used 1 grain only of chloride of sodium to 700 grains of nitrate of silver, and the mixed nitric and hypochlorous acids, liberated at the end of seven weeks' uninterrupted exposure to daylight during February and March, were neutralized by 30 drops of a  $\frac{1}{2}$ -grain solution of caustic potash, equivalent to 1 32nd part of a grain of solid potash, which, compared with the amount of silver nitrate originally taken, stands in the ratio of 1 : 22,400. In another experiment, performed in Mr. McLachlan's presence, without the chloride, the acid liberated was so small in amount that 6 drops of a 1-grain solution of caustic potash proved more than sufficient to neutralize it; in this case the ratio stands as 1 : 56,000. These statements will illustrate some of the difficulties encountered in the chemical investigation, and would lead one to hesitate in adopting Mr. McLachlan's assertion that nitrate of silver in pure aqueous solution suffers decomposition on exposure to light.

Another point upon which he would offer an observation was the alleged precipitation of the iodide of silver. In his experience this had never taken place. He would not enter into detail as to his reference to ozone; but would simply remark that Mr. McLachlan was under a mistake as to the nature of that body. He had described his theory as embracing an idea that "oxygen was absorbed by the silver from the water, actinism, and heat combined, changing it into a kind of ozone." Now, if his (Mr. Spiller's) notions of chemistry were right, ozone was an allotropic condition of oxygen. Silver could not take oxygen from water, because the affinities lay in an opposite direction; but if the silver could take oxygen from the water, it would form oxide of silver, and liberate hydrogen, the presence of which would be incompatible with the generation of ozone.

Mr. HOOPER said it would be somewhat premature to come to any conclusion on the subject at present. He thought the idea of adjusting the collodion, bath, and developer to each other was very important. As to the use of acetic acid in the nitrate of silver solution, he objected to it as generally increasing exposure. Without entering into details he thought all would be agreed that Mr. McLachlan had done a good thing in bringing his process before this Society, where the knowledge of scientific men being joined to his own practical experience, the best results might be hoped for. He did not quite agree with Mr. Fry as to the competency of photographers generally, as, within his knowledge, much uncertainty prevailed. He thought that photographers would gain by keeping at least three or four baths constantly in use, so as to avoid over-working any of them. He should like to know if Mr. McLachlan had tried working his baths, seeing that boiling the developer was so useful; in his experience he found boiling as good as sunning.

Mr. McLACHLAN had not expected that he would be believed at once. All he wanted was attention, examination, and experiment. If he were wrong he was the only loser, as he had spent much time in the experiments, and money also, as well as in his present efforts to bring the matter before photographers. As to Mr. Fry's statement that photographers were better informed than he gave them credit for, it might be; but he could only judge by the published information. It was quite possible, and he was disposed to believe that much more information existed amongst practical photographers than was to be found in the journals. Mr. Davis said he used excess of acetic acid in his developer, but this was an error. It had been reported in some of the journals that he used  $3\frac{1}{2}$  ounces of acetic acid in 16 ounces of developer, but this was a mistake, he only used  $3\frac{1}{2}$  drachms.\* As to the collodion he knew he was right in what he had said. He had made 6,000 samples of gun-cotton, and had cart-loads of it by him; he had made many more thousands of samples of collodion, and therefore spoke with experience. It was an error to suppose that his was simply a neutral bath. It was a bath distinct from any other usual bath, and would dissolve a very large amount of oxide of silver. Mr. Spiller's experiments did not meet the case; his

two baths were not put out at the same time, and that which was spoiled, instead of receiving 6 drops of the potash solution, had had a much larger quantity. Mr. Spiller poured quite a gulf of the solution into it. He repeated that his was a bath different to any that photographers had hitherto imagined, as they would find if they would only experiment.

The CHAIRMAN said it was scarcely necessary to ask them to give their hearty thanks to a gentleman who had taken the trouble Mr. McLachlan had done to bring his experiences before them. He could confirm the remarks as to the importance of maintaining, as nearly as possible, uniformity of temperature in all the preparations, as it accorded with their photographic experiences at the Royal Observatory. He thought, perhaps, it was probable that Mr. McLachlan scarcely did justice to the skill and success of practical photographers of reputation. He had been struck with the uniform excellence and freedom from defects of all kind in one plate after another in long succession. Possibly these practical men might not have published all they knew, as it was sometimes difficult in matters gained by experience for a person to say exactly what he did know. However, they would heartily thank Mr. McLachlan.

Thanks were accorded by acclamation.

The CHAIRMAN, in offering Mr. McLachlan the thanks, asked him on some other occasion to let them have his experience in a tabulated form.

Mr. McLachlan promised, and hoped the Society would appoint a committee to test his mode of working.

The CHAIRMAN called attention to the specimen of the presentation picture which Mr. Robinson proposed to give to the members.

Mr. DUNMORE promised to bring before the next meeting a tent, and Dr. MANN promised to exhibit some examples of the work of Professor Piazzi Smyth.

The meeting then adjourned.

#### LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

The ordinary monthly meeting of this Association was held on Tuesday evening, the 28th ult., at the Free Public Library, William Brown Street, Mr. J. HENDERSON, Vice-President, in the chair.

The minutes of the previous meeting having been read and confirmed, Mr. Joseph Sillitro was elected a member of the Association.

Mr. GREEN called attention to the great number of pictures on the table, all of which had been taken this year. He remarked that he attributed the fact of so much work having been done so early in the season to the simplicity of the collodion-bromide process.

The CHAIRMAN recorded his experience with various toning solutions, advocating phosphate of soda, which he had taken into use in preference to carbonate. He had used acetate of soda, but preferred phosphate.

Mr. BOLTON remarked that acetate of soda was the most economical, especially for amateurs.

Mr. GREEN had used acetate of soda for some time, and certainly found it the most economical; but he had given it up in favour of carbonate, which was more convenient.

The CHAIRMAN said he would like to ask the opinion of the members with regard to the action of light upon collodion-bromide plates after fixing and varnishing. He was inclined to think that exposure to light in printing had the effect of rendering the negative more dense; and he had intended making an experiment in that direction, but had not had time to do so.

Mr. PURPS said he had made the experiment, some time ago, of exposing a negative to the light for about three weeks, with one-half covered with non-actinic varnish; and at the end of that time the colour was changed all over the plate from brown to purple, but no difference could be detected between the two halves.

Mr. GREEN's experience led him to state that the negatives do intensify after fixing, to a certain degree, and that the same effect is noticeable in wet plate negatives developed with an organic developer. It was a peculiarity which need cause no inconvenience, and might be easily met by exposing the negative to sunlight before varnishing, when, if rendered too dense, it might be reduced with cyanide.

Mr. LEWIS HUGHES passed round a print from a negative taken a few days previously upon a Hill Norris plate which he had had in his possession upwards of seven years, and which had apparently suffered little by its long keeping.

\* Mr. McLachlan undoubtedly said in the meeting  $3\frac{1}{2}$  drachms of acetic acid, and we find it so stated in the shorthand notes; but he subsequently, in a conversation with ourselves, in which we asked him to verify the formula, corrected the former statement, and said  $3\frac{1}{2}$  ounces; hence the confusion.—Ed.

The Rev. S. BYRN brought forward an arrangement by which the ordinary portrait-camera might be adapted to the purposes of enlarging and printing.

After some remarks upon the definition of enlarged pictures, Mr. LEWIS HUGHES said the lenses he used for enlarging were Dallmeyer's triplet of 7 inches focus, and the ordinary single lens of 6 inches. With the solar camera he obtained the finest definition with the single lens, but with diffused light the triplet gave the best results. He also said that with ordinary lenses it was very difficult to produce negatives suitable for enlarging, and that two negatives, which to the eye appear equally sharp, frequently give very different results when enlarged.

Mr. ROBERTS thought that if, in focussing, a magnifying power of 3 or 4 diameters were used, the negative, when enlarged to that extent, would be as sharp as it appeared on the focussing-screen.

In reply to a suggestion that opal glass placed in front of the negative would give a beautifully diffused light for enlarging,

Mr. HUGHES said that the employment of opal glass in the manner suggested would cause such an immense loss of light, that enlarging to any considerable extent would be impossible.

Mr. W. H. WILSON thought that if the pocket camera found its way into general use, some process would have to be adopted, based upon the employment of albumen instead of collodion, in order to obtain the best results, in consequence of the great difficulty of obtaining a film of collodion sufficiently structureless for enlarging purposes.

Mr. GREEN said that collodio-bromide, if properly prepared, might be used with advantage, the film being extremely clear and transparent. If, in making the collodion, alcohol containing a large proportion of water were employed, such collodion would be useless for enlarging.

Mr. HENDERSON thought that a great deal as regards the density of the collodio-bromide film depends upon the length of time allowed to elapse between the preparation of the collodio-bromide and coating the plate. Opinion seemed to differ as to the exact time necessary, but it was generally understood that the longer the mixture was allowed to stand after adding the silver (of course within certain limits) the denser would be the resulting film: the length of time he (Mr. Henderson) generally allowed was three or four hours.

Mr. BOLTON said that the majority of the plates he had exposed this year were prepared within an hour from the addition of the silver to the collodion.

Mr. ROBERTS said he would like to ask Mr. Bolton what quantity of silver he used under such circumstances.

Mr. BOLTON, in reply, stated that he had always used 11 grains to the ounce, except upon one occasion, when, having used 12½ grains, he could not develop a picture.

Mr. HUGHES asked if any of the members had used the permanganate of potash plan for "doctoring" baths. He had three or four baths which were afflicted individually with all the faults it was possible for a bath to possess. They were mixed together, and were in an equally bad state. Altogether the quantity was about 80 ounces, to which he added two fluid drachms of a 10-grain solution of permanganate of potash, allowed to stand for 24 hours, and then filtered. The result was a bath without a fault.

The CHAIRMAN had "doctored" a bath of 40 ounces in the same way. It was not, however, so sensitive as a new one.

The first out-door meeting was discussed, and referred to the council.

The presentation pictures were distributed to the members present, the subjects being Frith's "Rosenlani," and three of G. W. Wilson's cabinets, York Minster, Loch Katriue, and Loch Tummel.

## Correspondence.

### PHOTO-LITHOGRAPHY.

SIR,—In the News of May 8th, a very personal letter appears, signed Dinsdale and Co. (the signature, by-the-by, like the letter, is, I believe, a mistake). The personal part is not worth much notice, as coming from a pupil to whom, as well as to his then manager, I taught litho-photography gratuitously. Part seems to be meant for you, Mr. Editor, and some one else, because, as I have not had the pleasure of holding conversation with you for some months (and certainly I have

not written to you about silvering stones), the sarcasm identifying me as your "authority" is without meaning. Now, sir, may I guess the name of your "authority?" I should say it was Common Sense. I would like your readers to note those two statements made:—"An apprentice in lithography will be in a position to explain as to what the effects of lithographic chalk may be when being put upon a silver surface, or indeed any other surface but the cleanest surface of the stone itself"—"and therefore will confine ourselves simply to the declaration that our productions are the results of photographing direct on the stone with materials capable of yielding proofs in printers' ink only." The clear inference which any one would draw from the above statements is, that the prints in question are obtained direct on the stone by photography without hand labour. This I candidly admit I do not believe, for in addition to my own experience on that point, I have been favoured with the unasked opinion of a well-known lithographic artist, who told me how they were produced; and he requests me to give his statement in contradiction to the declaration in the letter referred to. And he further offers to present to you, free of cost, for the benefit of your readers, a portrait on stone of any well-known celebrity you may select, which shall be produced in your presence if convenient to you, by that silver process declared to be so absurd; then it will be competent for your erratic correspondent to fix upon your "authority."—Yours respectfully,

W. GRIGGS.

[We shall have much pleasure in arranging to be present to witness the production of such a portrait for our readers.—Ed.]

### MODIFIED HONEY PROCESS.

DEAR SIR,—Hastily replying to "M. N. L.," I can only repeat my original directions so to mix the honey and water as to "make a thin syrup." Samples of honey vary so much that a precise formula suited to one sample would not give a sufficiently limpid product if used with another.

The syrup should flow *easily* over the plate, and be about the consistence of a mixture of equal parts of pure glycerine and water. Two drachms of *pure* animal charcoal will be sufficient for a pint of the solution (or syrup).

The plates will keep from four to twelve hours, according to temperature; and I do not think it at all a matter of consequence at what part of this interval the exposure takes place. Still, after some hours' keeping, I should expect a slightly-increased exposure to be advisable. I have not in any case found any flooding with water to be necessary, simply commencing to pour on the developer in the ordinary way. Owing to the presence on the film of a considerable portion of free nitrate, care must be taken, in using an iron developer, to avoid stains; but I recommend the gelatin-iron developer now, although I have not yet had an opportunity of trying it.—I am, dear sir, yours truly, in haste,

GEO. ROBT. FITT.

## Talk in the Studio.

NATIONAL PHOTO-ZINCGRAPHS.—It is stated that the publication of the National Records of England and Scotland will probably be completed in the course of the present year. It is proposed then to publish the facsimiles of National Records of Ireland. There is a steady demand for the facsimile of Domesday Book; the sum of £3,556 has been expended in the publication, and at the end of February £1,938 had been received from the sale of copies, and the copies in store would produce £1,900, so that the sale would more than cover the cost of publication.

THE ABYSSINIAN EXPEDITION.—The last report of General Napier says:—"The photographers have been employed in photographing, printing, and mounting plans executed by the Quartermaster-General's Department of the route followed by the army; these plans are used as distribution maps. All the baggage of the army having been left at Lat, the photographic apparatus was left there also, but has been ordered up."

PHOTOGRAPHIC NOVELTY.—If, as a general fact, we admit that "there is nothing new under the sun," our readers may well be

startled in these days by the idea of a photographic novelty. Indeed, it is difficult to say in what branch of art, science, trade, commerce, amusement, &c., photography does not play an important part. It brings with equal facility within the ken of tarry-at-home travellers the most inaccessible Alpine solitudes, and the soft luxurious repose of Italian lakes. It renders the features of every celebrity of the hour, from Mr. Gladstone to King Theodore, familiar to the public eye; and every policeman carries in his pocket the pictures in little of the ticket-of-leave men who, by the amiable weakness of justice, are let loose upon his beat. Trade, however, has taken a hint from Scotland Yard. We have before us a circular stating that a certain individual, in a particular business, has commenced for himself, and enclosing a carte-de-visite of the enterprising tradesman; from which, he says, the ladies to whom he sends his circulars and his portraits "will doubtless recognise him, on account of the active part he took in the business of," &c. It need not be added that "devotion to business," and "undeviating attention to the wants of customers," are expressed in every feature of this interesting masterpiece of photographic art.—*Standard*.

**FINISHING PRINTS.**—The following method for varnishing photographic prints is recommended by a correspondent of the *Archiv*:—"A piece of plate-glass is heated, and, while yet warm, a little wax is rubbed over by means of a piece of cotton-wool; water is then poured over the plate, and the moistened picture laid thereon and pressed closely down by means of a piece of filtering-paper. When dry, the picture is removed, and will be found to possess a surface of the greatest brilliancy, which is not injured by the process of mounting."

**BALLOON PHOTOGRAPHY.**—A correspondent is working a plan for photographing all around at once. He mounts eight cameras in a balloon, pointing in different directions; and when his balloon is at the proper height he exposes eight plates simultaneously. In case of war, he thus proposes to secure a quick view of the country all around any given point.—*Philadelphia Photographer*.

## To Correspondents.

**L. T. C.**—We stated that the new intensifier consisted of a solution of permanganate of potash; this is Condry's red fluid. The green fluid is a solution of the manganate of potash.

**W. STURGEON.**—The peculiarity you describe is not uncommon. It frequently happens that when methylated ether is used, the collodion, when first mixed, often acquires a deep colour from the liberation of iodine, and afterwards becomes quite colourless from the reabsorption of the iodine. On further keeping it is probable that the collodion will again acquire colour from the liberation of iodine. If any tendency to fog is manifest, add a little tincture of iodine; there is nothing whatever objectionable in the proceeding.

**W. CROUCH.**—You have begun on a difficult subject. It is very difficult to get a good copy of a photograph on albuminized paper. The really effect to which you refer arises from the light reflected from all the little inequalities of the surface giving an exaggerated effect of texture. It is better to begin by taking actual objects or persons, rather than copies. But if copying be more convenient to you, try your hand upon an engraving, which is much easier than a photograph to copy. Send us prints from the other negatives of which you complain, and we can probably advise you as to the defects and remedy.

**W. J. A. G.**—It is probable that some of the dealers can procure for you Hancock's india-rubber canvas and solution; but we do not know of any dealer by whom the materials are kept. So far as our memory serves us, the manufactory is in Goswell Road. 2. A strong shellac varnish answers well; or a mixture of plain collodion and boiled linseed oil. 3. The glass rod of which you speak may be made useful; in our own practice we find that by carefully and gently raising the paper from the bath, very little superfluous solution is brought away, and that a very slight draining effects every purpose. 4. For stereoscopic work, a lens (to a single lens we refer) of 6 inches focus would be more useful than one of 4½ inches focus.

**THOMAS STORHARD.**—You do not state the history of your chloride of gold solution; but we think it probable that it is some you have made from which the acids have not been sufficiently evaporated to begin with, and the solution still contains considerable free nitric and hydrochloric acid. Try proceeding as follows:—Take of the stock solution a quantity containing a grain of chloride of gold, and add carbonate of lime freely to neutralize the acid; then, in an open vessel, add 5 or 6 ounces of boiling water, and let it stand for an hour or two to cool. Then try it for toning, and let us know the result. 2. We shall publish the formula when we receive it.

3. We are glad you like the articles. Something on the subject of your enquiry shortly.

**ZENO.**—You cannot commit the common and probably natural error of the very young student. You wish to have a simple formula, instead of having to master principles. Instruction how to act in some particular case or cases is of little value, because of limited application; but a knowledge of principles, giving new results in every varied form of application, is of much higher value. When you have studied more, and more carefully, you will feel less disposed to dictate as to what you will be taught or how you will be taught. At present, it is clear that you have not studied, but only skimmed a little here and there, which is worse than useless. There has been no such attempt as that to which you refer.

**N. JOCELYN.**—The letter to which you refer never came to our hands. Mr. England intensifies with pyrogallie acid, with acetic acid, and a few drops of silver solution. There appears to be no difficulty in getting intensity. 2. The cotton is generally obtained, we believe, in Paris, at the *Maison Sennez*. Thanks for the suggestion as to using imperfect plates, which we shall insert shortly.

**C. B.**—Mr. Maxwell Lyte's rapid or "instantaneous" process with honey was published in the second volume of the *Photographic Society's Journal* in 1851. 2. The charcoal is to remain in the mixture during exposure to light. 3. The charcoal should be in powder, and will, of course, on first mixing with the honey, &c., make it like ink. 4. No; the silver must be in the mixture during the process of sunning. 5. If you want a preservative process as distinct from a dry process, yes.

**SILEX.**—It is scarcely fair to ask us what are the drawbacks of our collodio-chloride process as compared with the albuminized paper process. We might, with the partiality of parentage, answer, none. We will, however, as briefly as possible, give you some reasons why our process is not, and probably never will be, so extensively used as the albuminized paper process. Collodion is more expensive than albumen; therefore the cost of the process is somewhat greater. Albuminized paper can be purchased ready prepared, and all the following manipulations are easy, simple, and familiar; preparing the collodio-chloride, and coating the paper, require more care and skill. The collodio-chloride process, not having been invented by some one having a commercial interest in working it out, or pushing it, and filling the market with the preparation ready for use, persons interested in it have had to prepare their own materials, and work out the necessary conditions of each batch they prepare. Nothing gives a thing such a fair trial as some one having a commercial interest in its success. For these and other reasons it has not become, and is not likely to become, as popular as the albuminized paper process. Being free from silver in the whites, the prints have a better chance of permanency than albuminized prints, and the pictures are more delicate. 2. When a silver print fades, the blacks generally become a greenish brown, and the whites a dirty yellow, and so contrast and purity are lost. In some bad cases we have seen little remain beyond a faint trace of a yellowish image. 4. A transferred negative on any thin, flexible substance requires care, of course, or it might be injured by creasing. Letters referring to advertisements do not come under our attention, and questions for answer in this column sent in such letters are likely to be overlooked. When you require information on photographic matters, address the Editor in a separate letter. To secure answers the same week, a letter should reach us on Wednesday, as we go to press on Thursday, and the space is generally filled by that day.

**HENRY WILLIAMS.**—The sky may be blocked out in various ways: a piece of thin blackened silver paper, carefully cut and attached to the negative, affords a useful mask for the purpose, and one which we prefer. 2. A saturated solution of gallic acid is the proper developer for enlarged prints. Sometimes a little acetic acid is necessary, and sometimes a drop or two of nitrate solution; but these depend upon the condition of the print, and the judgment must dictate their addition. 3. The formula we recently published as employed by Mr. Solomon is an exceedingly good one.

**J. C. STEPHENS.**—Decomposition has undoubtedly taken place in the silver solution. We will write.

**GERMANIUS.**—The second letter and duplicate draft received. The copies of the *News* have already been sent. The book in a few days. Answers to the various questions shortly, when we have had time to examine the specimens and report on the points raised.

**AN AMATEUR.**—There must be some exceptional element in the case. Collodio-bromide plates, in our experience, keep well. We have exposed them some weeks after preparation without perceiving any deterioration. Such a loss of sensitiveness as you state to have occurred in three days puzzles us. We believe the Liverpool Company's collodio-bromide plates keep good for months. 2. Collodio-bromide is not suitable for printing on paper in the same manner as collodio-chloride, because the image of reduced bromide is weak and grey, possessing much less vigour than the image obtained by reduced chloride. 3. We have not yet received further details.

Several Correspondents in our next.

We are again compelled to leave over until our next several important articles in type, owing to the pressure upon our pages.

### MR. McLACHLAN'S DISCOVERY.

PENDING the three months' preparation necessary for an experimental verification of Mr. McLachlan's mode of working, a few words on his recent communication may not be out of place. His candid, outspoken manner of dealing with the whole subject; the unhesitating opinion he has expressed of the prevalent ignorance amongst photographers and the imperfect information of journals, entitle him to candid and outspoken rejoinder. Complimentary platitudes are out of place under such circumstances. They would be unfair alike to Mr. McLachlan and to photographers. It is due to both that if this gentleman be right, an ungrudging acknowledgment should be made of the fact; that if he be wrong, his error should be unhesitatingly pointed out. As we have already said, we give Mr. McLachlan credit for the most perfect honesty of intention, and not only purity, but liberality of motive. We believe him to have been an earnest, self-sacrificing experimentalist; and the effort and expence undertaken, at his own sole cost, to bring information, which he believes to be important to the progress of the art, fully and freely before his brethren, ought to entitle him to their careful attention. If he be proved to be in error, the cost and the mortification are all his; if he be right, the gain is that of the photographic community.

At the outset, however, we deny in the strongest terms the nature and extent of the ignorance and incapacity which Mr. McLachlan attributes to photographers generally and to photographic journals. On theoretical questions we admit that much remains to be determined; on practical points we admit that uncertainties at times exist, and that we should have thankfully received information which would have set aside some of the difficulties which occasionally beset the ablest men; but we deny that the majority of professional photographers of any position are groping in the darkness, or struggling with the vagaries which Mr. McLachlan so forcibly pictures, and we simply appeal to facts in reply to his allegation. Let us examine the practice of any photographer whose name and work are known. Take that of Francis Bedford. When he travelled in the suite of the Prince of Wales in the East, working the wet collodion process on large plates, under the greatest possible difficulties and disadvantages, without the power of remaining as long over each subject as he chose, without the power of revisiting the scene of any negative to repeat his operations if desirable, did he fail, or return without a good picture of any one of the important objects visited? On the contrary, he brought home, after his hurried trip, one of the most perfect collections of Eastern scenery that could be desired, charming as pictures and perfect as photographs. Whatever the difficulties, there was the practical issue. Mr. Frank Good has recently repeated a very similar task. Mr. England has for years past, in mountain and valley,

crowded street or lonely glen, worked with a precision of which the number and excellence of his published works are the best evidence. We might extend the list to include the name of every landscape photographer of position, and we especially mention these because working in tents and with travelling equipments involve difficulties little dreamt of in the studio. Then, if we were to mention the portraitists who, in daily practice, produce in regular succession any number of perfect negatives, we might fill many columns of these pages.

Mr. McLachlan's allegation as to the absence of information in the journals we might be content to pass without comment, as probably done without thought of the insult it conveyed to the gentlemen of the highest rank as chemists, artists, and practical photographers, who have from the commencement contributed the results of their study and practice to societies and journals. If the journals have been deficient in information it must be because the ablest men connected with the art are either incapable or dishonest, for there is not an illustrious name in photography which has not been attached to contributions in the journals. We are afraid that this allegation, like some others, was the offshoot of imperfect knowledge. We asked Mr. McLachlan what journals he had been in the habit of reading; and learnt that, until very recently, he had *not* been a reader of the PHOTOGRAPHIC NEWS!

We were reminded of the anecdote of a chemical student calling upon Faraday with a discovery he alleged he had made. "Have you read the published authorities on this subject?" Faraday asked. "No; believing I had made an important discovery, I did not like to waste time in consulting books," was the response. "So," responded the great philosopher, "you come to waste my time by bringing under my attention experiments which are already well-known, and published. In future, when you think you have made a discovery, before announcing it, make yourself master of what has already been published."

On the subject of uncertainty in working let us not be misunderstood; every photographer has occasional difficulties; but the more prudent the practice, the fewer the occasions, as we shall presently show. The very nature of the circumstances necessarily involves occasional uncertainty. The photographer works with materials prepared for him of the exact nature or condition of which he can never be quite certain. The soluble cotton is a material peculiarly liable to slight variations of constitution; the ether and alcohol peculiarly liable to traces of varied impurity, and peculiarly liable to change; and these, when mixed and iodized, are liable to other and complex changes dependent on conditions and time of keeping. Although pure nitrate of silver may be easily obtained, and a good bath made, that bath must—however perfect the materials, however comprehensive the knowledge employed—be constantly changing in constitution,

Silver is abstracted from it by every plate immersed, and nitrates of the base employed in the collodion and iodide of silver, as well as ether and alcohol, constantly accumulate and furnish the elements of other and complex changes. These and other elements of uncertainty exist with the purest materials and the most perfect conditions, and are inherent in the process. The wonder is, not that uncertainties exist, but that, with so many elements of change not under strict control, so much good work is done with so much precision and regularity by so many photographers.

Further, we must contend that if much greater difficulty and uncertainty existed than really does prevail, the remedies proposed by Mr. McLachlan can in no way tend to greater certainty. The basis of his proposal is the use of an impure sample of nitrate of silver, of unknown impurity, difficult to procure, and still more difficult to identify. Need the conditions of uncertainty be carried further? We need not dwell on the uncertainty involved in adding one empirical remedy to various collodions of unknown and varying constitution, nor to the uncertainty involved in using by preference sulphate of iron of unknown impurity.

We have on a former occasion remarked, we may be reminded, that assuming the facts stated to be true, they were important and interesting. This is undoubtedly true; but they do not furnish remedies for any of the inherent uncertainties of the collodion process. If it be true that a solution of nitrate of silver undergoes a change, under the prolonged action of sunlight, other than that already recognized, and that, in consequence, it acquires a property, not only of holding a large portion of oxide of silver in solution, but of preventing it being readily reduced, the fact is both interesting and important, inasmuch as, if true, it must lead to more rapid, and, possibly, more perfect results; but it affords no immunity from the constant changes going on in collodion, the constant accumulations and change of condition in the nitrate bath, the constant possibility of the action of impurities beyond the control of the photographer, and the varying other elements of change and uncertainty which are the chief sources of the troubles which occasionally beset the photographer. If the fact stated by Mr. McLachlan, that a bath treated as he describes suddenly and of its own impulse eliminates from itself excess of iodide of silver, it is very important and interesting, as getting rid, not of an uncertainty, but of a certain source of occasional defect, with less trouble than is involved in the method of diluting and filtering.

But without denying Mr. McLachlan's facts, which can only be verified or disproved after many months of careful experiment, we may point out that there are certain considerations in regard to them which require weighing. In the first place, the best evidence he could have furnished to a meeting (experiment being impossible) would have been a sight of some negatives of exceptional excellence. We know that Mr. McLachlan is a capable practical photographer, and produces fine negatives, as do most photographers of position; but the gentlemen present at the Photographic Society would not have been slow to recognize any exceptional qualities.

Further, there is already a difference of evidence on the facts. Mr. Spiller states that a bath prepared according to Mr. McLachlan's instructions, and sunned for seven weeks, was made alkaline and unfit for work by the addition of 6 drops of a 1-grain solution of caustic potash, the proportion of the alkali to the silver salt being as 1 to 56,000. Mr. McLachlan states, that instead of 6 drops, "quite a gulf" of the potash solution was added. A mistake exists somewhere, and we leave our readers to select between the precision of a gentleman of long experience as a practical chemist, accustomed to attach value to infinitesimal proportions, and that of Mr. McLachlan, who is certainly an impulsive and enthusiastic gentleman, although, as he says himself, no chemist.

And here we have a word of grave remonstrance for Mr. McLachlan, which he must take in good part, as it is written

in a friendly spirit. He prefaced his last communication by stating distinctly that he was no chemist, and he then proceeded, not simply to state the facts of his experience and observation, but to indulge in a series of theoretical speculations of the most incongruous character, and to speak of chemical reactions of the most impossible character. We forbear giving examples; but we suggest that we are prepared to listen attentively to the observations and experiences of Mr. McLachlan as those of a gentleman who has worked hard and enthusiastically in experimental photography, and whose work, guided by more chemical knowledge, would have been more valuable; but we must ask him to avoid encumbering his facts with chemical terminology misunderstood and theory misapplied, as these things materially impair the practical value of his information.

Having pointed out—with the candour for which he asks—the misconceptions which we think Mr. McLachlan has laboured under as to the existing knowledge of photography, and his somewhat erroneous estimate of the scope and bearing of the facts he has stated, we shall in our next have a few words on the real importance and value of his communication, which, notwithstanding the errors we have pointed out, contains much suggestion for which photographers will be obliged to him.

#### SWAN'S CARBON PROCESS.

NOTWITHSTANDING the large number of excellent carbon prints which have been issued by Mr. Swan from his establishment at Newcastle-on-Tyne, and the fine examples which have been exhibited by Mr. Mayall, Mr. Cherrill, and others, we learn from personal and written communications with photographers that a doubt exists in some quarters as to whether these things are indications of anything more than exceptional success, and whether, after all, the carbon process can be generally worked with success as a commercial enterprise.

It will interest photographers generally, and especially those who have doubted the practical character of the carbon process, to hear of the progress of this mode of printing at the establishment of M. Braun, of Dornach. It is not much more than two years, if we remember aright, since Mr. Swan's process was inaugurated at Dornach. During that time it has been gradually developed, and has displaced silver printing. The number of persons now regularly engaged in the establishment in the production of carbon prints is eighty; and the demand for the pictures is so great that, with this large staff, M. Braun finds it impossible to accumulate stock, the demand being in advance of the production. One fact like this is worth a hundred arguments on the practical and commercial character of carbon printing.

We hope ere long to see this mode of printing as extensively in use in this country. The "Autotype Company," to which we have before referred as having acquired the patent of Swan's process in this country, is steadily progressing with arrangements for an exceedingly perfect and extensive system of art reproduction by means of carbon printing, which promises more for the popularization of really good art, and giving the examples a permanent form, than has ever yet been attempted in this country. The results now exhibiting at the company's gallery in the Haymarket leave no room for doubt as to its success.

#### PICTORIAL EFFECT IN PHOTOGRAPHY;

BEING LESSONS IN

COMPOSITION AND CHIAROSCURA FOR PHOTOGRAPHERS.

BY H. P. ROBINSON.

CHAPTER XVII.

"Every man is always present to himself, and has, therefore, little need of his own resemblance, nor can desire it but for the sake of those whom he loves, and by whom he hopes to be remembered: this use of the art is a natural and reasonable consequence of affection, and though, like other

human actions, it is often complicated with pride, yet such pride is more laudable than that by which palaces are covered with pictures that, however excellent, neither imply the owner's virtue, nor excite it. Genius is chiefly exerted in historical pictures, and the art of the painter of portraits is often lost in the obscurity of his subjects; but it is in painting as in life: what is greatest is not always best."—*Dr. Johnson.*

"Blest be the skill which thus enshrines the great,  
And rescues virtue from oblivious fate,  
Which seems to fix the falling stars of mind,  
And still preserves their lustre to mankind."

*Sir Martin Shee.*

#### PORTRAITURE.

PHOTOGRAPHY has been employed to represent everything under the sun, and that is illuminated by his light; nay, it has gone farther than this, it has brought pictures out of the caves of the earth, where the light of heaven never enters, and where the only source of actinism has been coiled up in a wire; it has even compelled the pyramids of Egypt to give up some of their secrets, and the catacombs of Rome pictures of their dead. The earth, the sea, and the sky it delights to render; it multiplies the works of genius, whether the original vehicle has been paint or marble, or that "frozen music" of which the great architects of old piled up their marvellous temples. The pirate and the forger have called in its innocent assistance to help them in their dirty work, but for which photography has returned the compliment by assisting justice to execute the law; and so truthful does the law consider its evidence, that it is accepted as an unquestionable witness which it would be useless to cross-examine; it helps the trader to advertise his wares, it aids the astronomer to map the stars, and compels magnetism to write its own autograph; and all this in such a way as no other art has ever yet approached. But of all the uses to which it has been put to benefit and delight mankind, none can compare with its employment for portraiture, the chief object to which its inventors intended it to be applied, and for which it appears to be most thoroughly adapted.

The portrait has always been the favourite picture with the world. It is an especial favourite in England, because it appeals to the domestic sympathies; and this is the most domestic nation on earth. Johnson is reported to have said he would rather have the portrait of a dog he knew than all the historical pictures ever painted. Horace Walpole gives excellent reasons for preferring portraits to other pictures: "A landscape, however excellent in its distribution of road, and water, and buildings, leaves not one trace in the memory; historical painting is perpetually false in a variety of ways—in the costume, the grouping, the portraits—and is nothing more than fabulous painting; but a *real* portrait is truth itself, and calls up so many collateral ideas as to fill an intelligent mind more than any other species of painting."

Without disparaging other branches of art, as the author of the above sentence has done, there is no doubt of the extreme popularity of the portrait, and photography has only developed and encouraged a desire for representations of those we love, honour, or admire, by giving us the means of producing portraits, not only within the reach of the humblest purse, for their cheapness, but that we can believe in, for their truth. Before the birth of our art those who could not afford to employ a Reynolds, a Gainsborough, or a Lawrence, had to be content with the merest suggestions of likeness, executed in the most miserable style. Even when the portrait was painted by a master, it required considerable faith to enable a person who did not know the original to believe in the fidelity of the resemblance. The friends of Sir Joshua Reynolds often used to express their surprise that he had courage to send home portraits that bore so little likeness to their originals. And from his painted portraits we have nothing like the faith in the personal appearance of Shakespeare we should possess had we a portrait of him produced by photography. How are we to believe that the portraits of Lely are faithful likenesses of the ladies he painted, when they are so like each other that they appear to be one vast family of sisters? Kneller's portraits also appear like so many prints from one plate. Are we to believe that in the time of these two painters nature forgot her variety, or departed from her rule that no two men or women

should ever be the same in form, feature, colour, or proportion? This mannerism, which tended to destroy faithfulness in portraiture, injured, more or less, the works of all painters until photography came to teach them individuality.

The application of photography to portraiture has reformed and almost revolutionized that art throughout the world; yet ninety-nine out of every hundred photographic portraits are the most abominable things ever produced by any art, and the original may often truly say, with the old Scotch lady who saw her own portrait for the first time, "It's a humbling sight; it's indeed a sair sight." This is not the fault of the art itself, but of those who, on the strength of being able to dirty a piece of glass with chemicals, are pleased to dub themselves artists. The late depression in the trade has done good in one respect, if it has borne rather hardly on some: it has killed off the weak ones—those who never should have left the occupations for which only they were fit, to discredit, by their miserable productions, a noble profession; for photography is a noble profession, although it is a mean trade. Photography has hitherto been,—

"A mart where quacks of every kind resort,  
The bankrupt's refuge, and the blockhead's forte."

Again, the photographer has not often the advantage, enjoyed by the painter, of making the acquaintance of his sitter before he takes the portrait. He often sees him for the first time as he enters his studio, and has done with him in a short quarter of an hour. It requires great perception of character and great fertility of resource to enable him to determine at once, and at a glance, what is best to be done, what expression he should endeavour to call up, and what position would best suit his sitter. Great painters usually commence operations by dining with their subject, the value of which is shown in the following anecdote of Sir Joshua Reynolds, related by Leslie.

A matchless picture of Miss Bowls, a beautiful, laughing child, caressing a dog, was sold a few years ago at auction, and cheaply, at a thousand guineas. The father and mother of the little girl intended that she should sit to Romney, who, at one time, more than divided the town with Reynolds. Sir George Beaumont, however, advised them to employ Sir Joshua. "But his pictures fade," said the father. "No matter," replied Sir George, "take the chance; even a faded picture, by Reynolds, will be the finest thing you can have. Ask him to dine with you, and let him become acquainted with her." The advice was taken, the little lady was placed beside the great painter at the table, where he amused her so much with tricks and stories that she thought him the most charming man in the world; and the next day was delighted to be taken to his house, where she sat down with a face full of glee, the expression of which he caught at once, and never lost; and the affair turned out every way happily, for the picture did not fade, a phenomenon occasionally met with even in photography, and has, till now, escaped alike the infictions of time or of the ignorant among cleaners.

There are two morals to this little anecdote: the one is, that if all proper means are taken to secure a good portrait, glass-plate cleaning is not the first operation. The preliminary proceeding is to dine with your sitter; the disadvantage being, that the photographer's appetite should equal the extent of his business, which is not always possible, even in the present slack times. The second moral is, that the fading of pictures did not originate with photography. Sir Joshua Reynolds' pictures were known to fade even in his lifetime, which means that it is possible for paintings in oil to deteriorate quite as quickly as photographs. It is not much consolation to the kettle to know that the pot is also black, but it is comforting to know, as we have done for the last year or two, that there is no more necessity for photographs to fade than there is for paintings.

All this by way of introduction; I shall attempt to grapple with this difficult subject—portraiture—next week.

# ON THE TRANSFORMATION OF PHOTOGRAPHIC IMAGES IN SILVER INTO OTHER METALS AND COMBINATIONS; AND ON THE TECHNICAL APPLICATIONS ARISING THEREFROM.

BY WILHELM GRUNE.

I HAVE undertaken the experiments which I propose to communicate in these lines in order to make photography more practicable for industrial purposes; the good results which I got will, perhaps, induce others to undertake further experiments in this interesting and not yet sufficiently cultivated department. Where the photographer has finished the operations of his negative process, I begin my work by further chemical reactions on the silver image resulting from that process.

It is known that such an image is obtained by pouring a collodion containing iodide and bromide on a glass plate, which is immersed into a bath of nitrate of silver, afterwards exposed to light, and treated with sulphate of iron. In this process a precipitate of silver is formed on all parts which have been affected by light, whilst the iodide and bromide of silver, which have not been influenced by light, remain unchanged, and are removed by means of hyposulphite of soda or cyanide of potassium. The result of these operations is an image consisting of fine powdered metallic silver on an indifferent and transparent layer of collodion. It is a very peculiar fact that this image is not lying within the collodion, but upon it; thence follows, that it can be easily removed by the mere application of a finger and oil, without hurting the collodion. I make use of this property by transferring the inverted image on any other substance (as, for instance, wood, ivory, &c.), and removing the collodion by means of ether; the image, consisting of a very fine powder, remains on the surface employed to receive it. This process is of great importance for the manufacture of wood engravings; it removes the difficulty of drawing on wood, by which the original image is so often deformed; it is not necessary to treat the surface of the wood by itself; and in cutting no trouble arises from the process.

In the same way I get photographs totally free from fading, by transferring to paper images already converted to platina. Photographs of this kind have a very great likeness to engravings, and it is possible to get faithful reproductions of these by the indicated method.

By the expression "transferring," I mean removing the collodion film, with the image upon it, from the glass plate, and mounting it on another material, as china, paper, or other surface. This is effected by placing the glass plate, with the wet collodion on it, into water, which contains a little sulphuric acid. After a short time the film is removed from the glass, and may be cautiously transferred with a brush to any other fluid, and mounted on another support. In all operations which I propose to describe, I employ these films removed from glass; in water they remain unchanged for months.

In order to effect the chemical transformation of the image, I make use of the strong affinity which exists between silver and chlorine. The silver in the images decomposes most of the chlorides, and leads thereby to the proposed end; we can employ for this purpose such salts as are soluble in water, or other solvents, and are precipitated insoluble as pure metals or chlorides of a lower degree when they are deprived of their chlorine; I myself have employed chloride of platina, of gold, of palladium, iridium, copper, or mercury.

Chloride of silver being formed, the metals or sub-chlorides are precipitated insoluble, and, when chloride of silver has been removed by the well-known solvents, the precipitated matters remain, and form exactly the original image in all its half-tones, the substance of the latter being therefore changed.

Chloride of platinum changes the grey silver image into a dark image of platina black. If this be transferred to glass or china, covered with an enamel containing lead, and

then heated, the image burns in black. In this way I have got portraits and pictures on china and enamel for many years. If we employ a reducing flux, we receive images and drawings in the peculiar metallic colour of platina. Chloride of gold gives images of brown golden colouration, green when examined by transmitted light, which, when transferred to glass and china, and burnt in with a reducing enamel, give golden drawings, capable of receiving a metallic polish. On this principle I have based my photographic chemical method of decorating glass and china. The effects got in this way are of a very great delicacy, but do not show any half-tones, since gold, even in the greatest dilution, keeps its original colouration when it is looked upon, although it may be scarcely perceptible by looking through.

By the facility of making, by photographic operations, silver films of any thickness we please, and of transforming them into gold, it has become possible to precipitate gold as a metal in such a dilution as we have not been able to do before. More interesting than of importance for practice are—

Chloride of iridium, which gives dark grey drawings in the heat.

Chloride of palladium gives dark grey images, which very peculiarly, when burnt into china and worked upon with a polishing-stone, like generally gold and silver, show a brown colouration of metallic shine.

Chloride of mercury changes the silver images into white ones, consisting of chloride of silver and sub-chloride of mercury. When employed on photographic paper images it gives the well-known magic photographs. Such a white image placed upon a polished plate of zinc, copper, or steel, is readily decomposed by mere contact, even when dry; and when it has been removed the whole drawing remains on the plate, a circumstance which could be made use of by engravers in order to get rid of difficult delineating.

These white images are extremely sensible of hyposulphites, which they indicate still in a dilution of 1 to 600,000. They may therefore be employed as a proof of hypo, because they keep, unchanged, for a longer time under water. In a hypo bath the white image is changed into sulphide of mercury, of black colour. I employ this in order to get very nice effects on glass. If I bring such a film with a mercury image on it into water which contains enamel fluxes suspended, the spots struck by light absorb the fluxes, whilst the other parts of the collodion film remain indifferent. If this image is brought on glass into a high temperature, the sulphide of mercury is burnt away, and on the surface of the glass remains an image consisting of ground glass, and showing exactly the original drawing without any colouration.

A white image of sub-chloride of mercury treated with iodides receives a yellow colouration, iodide of mercury being formed. This is of importance for the practical photographer, if he likes to make weak negatives more intense. It is possible to work in direct sunlight with such yellow negatives, since the layers beneath are not heated so much as generally, which is of a great value for heliographic purposes.

Chloride of copper is precipitated as subchloride, which, when heated with sulphocyanide of ammonia and ferrocyanide of potash, receives a red colouration, changed into flesh-tint by being burnt in on faience and enamel.

I now give a further series of precipitations, which are of importance for the application of photography on burning into china and glass, because they enable us to produce different colours and shades by employing different fluxes. I suppose, however, that not only chemical reactions produce these colours, but that also physical properties of certain finely-divided metals have influence on the production: first of all, a red-brown precipitation, which, according to Mr. Selle, is produced by treating a silver image with a mixture of nitrate of uranium and red ferrocyanide of potash. An image transformed into platina-black gives

with the same chemicals a very agreeable brown image, which I have very often employed for making transparent photographs on white glass. A mixture of chloride of iron and ferrocyanide of potash is a brown solution: a platinum image placed into this fluid is immediately changed in a picture of Prussian blue precipitated. This is not the case with a silver image. When treated with caustic alkalis the image of Prussian blue is decomposed; platinum and oxide of iron remain. A silver image placed into a solution of permanganate of potash is immediately coloured a brownish-yellow; oxide of manganese being formed on the image.

As already stated above, these precipitations are not the only chemical ones, since there is no limit for precipitating. This circumstance affords to practice the advantage that every degree of decomposition and every tone may be got.

Great attention has been paid lately to chloride of silver, because it enables us to reproduce the natural colours by photographic means. This is especially the case with violet-chloride of silver. The production of the sensitive surface of sub-chloride of silver on silver plates or paper does not admit exact observations as to the origin of the colours, the acting film being always bound to a support, which is not quite neutral. By my method of transforming I receive, very easily, films which consist only of sub-chloride of silver supported by collodion or glass. As in the production of metallic silver images, I receive an equal surface of finely-divided silver on a glass plate by general exposure; I now change this into chloride of silver, leaving it on the collodion; or I first remove the collodion by burning, and then treat the silver directly supported by glass. As a means for transforming metallic silver into chloride of silver, I employ a mixture of diluted permanganate of soda with hydrochloric acid.

## ON THE ECONOMIC USE OF ARTIFICIAL LIGHT.

BY DAVID WINSTANLEY, JUNR.

SURELY no person who has ever witnessed the production of an enlargement by the lime, the electric, or the magnesium light, can have failed to witness with regret the enormous waste of illuminative and actinic power which takes place. I believe I may venture to say that no apparatus for such purposes is in use which does not involve the very serious drawback of loss of light in most lamentable quantities.

In the use of the electric and magnesium lights, for instance, each gives illumination to the extent of  $360^\circ$  in the horizontal angle, and nearly the same amount in the vertical, and yet it rarely happens in either case that more of all this vast quantity of light is utilized than that which suffices to cover a circle  $45^\circ$  in diameter.

In the case of the lime light the loss is not so great, inasmuch as  $180^\circ$  horizontal and vertical is the limit of available light. By-the-by, it is worthy of notice that when the cake of lime is thus sustained in such a manner as to give a full view of the back, there is as much light given off from this back surface as would suffice to illumine a decent-sized room, or quite sufficiently for domestic purposes. In any case, however, there is a vast deal more light lost than it is desirable there should be.

In the case of the magnesium and electric lights, I am surprised that a reflector should not have been employed, even at their earlier introduction. Many have tried, and one or two even asserted that they have succeeded, for enlarging purposes, with a parabolic reflector. How such a reflector *could* succeed is certainly more than the writer can perceive, and he is tempted to think that the assertion that it *did* succeed is—to use parliamentary language—"not altogether in accordance with the strictest veracity." Had a spherical reflector been used, the case would have been different, as, by placing the light in its centre, all the rays—both reflected and original—would have the same direction of divergency, and would, therefore, be capable of being brought to the same focus by the condenser, and of forming one image instead of two.

The accompanying sketch shows an arrangement in which Fresnel's lighthouse dioptric apparatus is combined with a spherical reflector for the purpose of utilising the largest

possible quantity of the rays proceeding from the electric or magnesium light, and which appears, in the writer's estimation, as being such as may be added to the enlarging camera with great advantage from an economical point of view. Care would no doubt be required in the construction of the lens of the dioptric arrangement, in order to distribute the light in one even beam; but care is also required in the construction of a portrait combination, and, indeed, in the construction of everything from which we reasonably hope to obtain any valuable results; and if this should prove to be the only objection to this form of apparatus, we shall, I hope, shortly see it in use for the purpose of producing photographic enlargements by artificial light.

## REMARKS UPON THE WET COLLODION PROCESS.

BY MR. MCLACHLAN.\*

I CAN assure you that it is with great diffidence I discuss this subject before gentlemen whose knowledge of chemistry and actual performances in their profession, so completely outstrip anything I have ever done; yet my love of the art compels me, if I speak at all, to speak the truth as it is in me. I am no chemist, therefore claim your indulgence in laying the following facts before you:—

In my opinion the common process has been tried and found wanting; no experience is capable of cheekmating its vagaries; nor can it be depended upon from hour to hour. I will only touch upon some of the points, and endeavour to show the cause of its instability, as well as the errors committed in working.

To begin with the bath, we are desired to iodize it with iodide of potassium or silver; this is very indefinite, for there is a great difference in its working, according to the kind of silver used, and the way it is prepared. What is wanted, I presume, is iodide or bromo-iodide of silver with an excess of nitrate, organic matter acting as an accelerator; if this is so, it must be very important indeed to obtain the iodide in a proper condition. I think this will be admitted; if not, try the following experiments, and you will soon be convinced:—Suppose you begin with neutral silver: into an ounce measure place one drachm of 35-gr. silver solution, into another measure the equivalent proportion of iodide of potassium; mix and wash, see the kind obtained; repeat the experiment with another drachm of silver, only adding one drop of weak nitric acid, of the strength of one drachm of acid to 6 ounces of water; again observe the iodide obtained; keep repeating this experiment, and you will find every time a difference in the iodide, each addition of acid

\* Read before the Photographic Society, May 12th.

making it less sensitive; reverse the experiment, and, instead of acid, drop into the silver 1 drop of caustic potash, 1 grain to an ounce of distilled water; do this five or six times, compare the iodides in appearance and working; the perfectly neutral giving by far the most certain as well as the most truthful results, the acid iodide giving thin pictures, and the alkaline giving unstable patchy ones that decompose the development. An iodide made from a concentrated silver solution will give a stronger picture than one made from a weak solution. When a bath is made, the water-bottles, &c., should be of an equal temperature, as near 60° Fahr. as possible. To prove this, take a rather acid silver, let the water be from 65° to 70°, iodize with iodide of potassium, dilute to requisite strength, and you are almost certain to have slightly streaked plates with indications of fogging. Such a bath will soon give hard pictures, especially if the precipitate of iodide has not been great; if it has, they will be even but rather more foggy; this is caused by the temperature separating the iodine from its base, free iodine causing fine streaks, the haste the fogging. Long rest or sunning will cure it of its fogging propensities. Should you add nitric acid to cure it your difficulties begin, because of it acting upon and decomposing the iodides in the collodion; for according to the state of the bath or collodion will you have one or other of the iodides described. Alkaline plates are often obtained from an acid bath, because of the collodion being made of strong alcohol and ether; the iodizer not being of the most soluble kind under such circumstances, decomposition or disturbance takes place in the plate while the iodide is forming; with an acid bath this is always so more or less. This tells me that for certainty and perfection of results, both bath and collodion should be neutral. By the common system of working this is not possible (at any rate for daily practice), but my way of preparing the bath allows this, as it gives the necessary firmness to the picture, as well as having the power to rectify any alkalinity in the collodion.

Every different kind of silver makes baths of different degrees of quality and stability, and this is not caused by any impurity, but is entirely owing to the state the crystals are in. Condition of chemicals is everything, and not—what might be supposed—actual purity. A clear, transparent, neutral, dull, and blue-looking crystal is the best of all; the semi-opaque, slightly alkaline, and white-looking, being the worst. Baths from this silver are not so lasting, nor do they generally give such clean pictures. This kind, even when perfectly neutral, is what I should call weak in constitution, and no addition of acid, however carefully added, will ever give it the same stability as the clear, deep-coloured, neutral crystal. The addition of acid helps to give it stability, but it does not answer so well as the proper crystals. The acid seems to act by itself, and to affect the collodion much more injuriously.

I will now examine the collodion, and see if it is likely to be in a proper condition for forming an iodide or bromo-iodide of silver in equivalent proportions when it is placed in the bath. For this to be possible it must be perfectly homogeneous; by that I mean there must be an atom of iodine in combination with an atom of base. This, I think, is very rarely if ever obtained, because of the action of the pyroxyline and the solvents upon the iodizer, for as much as we depart from equivalent proportions do we fail in obtaining, not only stability, but, more than all, truthfulness. Excess or separation of base gives hardness and a corresponding want of the power of rendering perfect anatomy. The free iodine, although serving to give clear pictures and reduce intensity, is constantly acting injuriously upon the bath. Neither the free iodine nor the separated base play any direct part in the formation of the image, but they are highly injurious in the nitrate bath, causing hardness and greasiness, and speedily destroying its good working qualities. Why cannot we obtain the iodizing solution undecomposed in the collodion? There are various reasons why this cannot be obtained: first, strong ether and alcohol will decompose the iodides more or less, according to their solubility; the pyroxyline that is generally used will decompose the iodides more or less, and so will the acidity or alkalinity of the solvents cause a precipitate of the iodides or the bromides, as the case may be. I shall, no doubt, be told that pyroxyline can be made that will not decompose the sensitizer. Of this I am aware; but it will often do worse in many ways not possible to be explained in this article. Very soluble iodides can also be used, but they give thin pictures; for remember, it is the state of solution of the iodide that is everything, and not the kind of iodide. Condition is everything; the more acid collodion is, the

more unstable it is as a rule. Now, the effect of introducing into the ordinary nitrate bath a collodion with a part of the base of the iodide free is to produce an iodide of silver in the wrong condition. According to the state of solution in which the iodide is in the collodion, so will the picture be flat, hard, or round; but it cannot be truthful, although it may be sometimes more pleasing than if it was so, hard features being favoured by an iodide that is easily soluble. Pyroxyline I will say nothing of, as the varieties are so numerous that I should only waste time by alluding to any; yet it is of more importance to photographers to thoroughly understand their different actions in collodion than is generally imagined. There is a revolution that will come from pyroxyline as great as any that I claim for my bath. When this is accomplished, as it will be, failures will no more be known but through carelessness, and never, until it is, can we have an iodide of silver in a perfect state.

There is now the iron solution, or developer. Nothing I have ever read has given me an insight into its different states or conditions; it has always been so many grains protosulphide, as if it was always of the same kind, any more than collodion is; I refer to the protosulphide alone, without the many additions it has from time to time been subjected to. There are just as many kinds of iron as there are of silver or collodion, and all guaranteed to be pure; and I have no doubt they are; for although there ought to be nothing easier than to obtain a definite pure crystal of iron, yet it is not so easy: for unless you purchase a lot at once, every different sample will produce a difference in the negatives. I will describe some different kinds:—No. 1 is a deep green crystal, dissolves quite clear, and keeps so for a whole day and night without the addition of any alcohol or acid. No. 2 is less deep in colour, dissolves clear, and keeps clear perhaps for a half-day. No. 3 is much lighter in colour; this is said to be absolutely pure; after it is dissolved it gets slightly muddy in about ten minutes. No. 4, common green copras, impure, at 1d. per lb., and such as is used by dyers, goes quite muddy even while it is dissolving. There are many other kinds of iron; but these are sufficient for illustration, every one wanting different treatment in its preparation; for every one of them is invaluable when its special qualities are known. Take No. 1, 15-gr. iron to 1 oz. water, to 16 ozs. of which add 5 drms. alcohol, pure spirit, and 3-2 drms. glacial acid; try to develop, and you will find that it will not flow evenly over the plate; No. 2, and the same until you come to the slightly muddy one, the pale-blue crystal pure iron; this will go evenly over. But see what a difference in their action: the iron that dissolves clear will give you a clear picture, but thin, because of the silver being washed away; the iron next in clearness, when dissolved, will give a more intense picture, principally because of its remaining more even on the plate; and those that dissolve milky, or become so after a short time, will give thin foggy pictures.

Now try an experiment: take any that keeps clear, dissolve in the same amount of water, add pure spirit, place the bottle in a saucepan on the fire with something to keep it from the bottom of the pan, fix the stopper loose, boil as long as you please (say for an hour or more); do this only for an experiment. Now, if you do not turn the neck of the bottle up the chimney before you take out the stopper, you will have the contents in your face.

The iron that dissolves next in clearness will be less liable to do this, and so on until you come to the kind that dissolves milky. With them there is no expansion of the alcohol at any consequence. How is this? Just because of the first samples of iron having more acid in them than the others, the alcohol being neutral, or perhaps slightly acid from ngo; in this state it will not amalgamate with an iron salt containing a trace of free acid.

Take the weak potash solution which is used for the collodion, drop two or three drops into the alcohol, add this to plain iron solution; now boil as much as you like; the alcohol, being homogeneous with the water, will not be separated; before they were merely mechanically combined, and, when placed upon the plate, naturally parted; now they will lay even. The iron salts that dissolve clear do not need to be decomposed by heat to prepare them for developing; and they will give the most dense pictures. About ten minutes' boiling will make the picture develop still more densely. Very long boiling (say one hour) will give you a very thin picture, but particularly clear. In a word, the irons that dissolve clear have more developing power; the muddy ones less, and so give much more half-tone. All the irons that dissolve the least

muddy, or get so after standing half an hour or so, should have the alcohol put to them, and heated more or less; when the iron is heated with alcohol, add the acid, after short boiling (say five minutes) gives most half-tone; up to half an hour, more vigour. The common iron used by dyers, when very slightly heated, just enough to slightly peroxidize part of it, gives by far the most half-tone of any, and is quite invaluable when your pictures are at all hard; your materials must, indeed, be in a bad condition if you cannot get perfect softness with this iron. This difference consists entirely in the different normal power of each iron to absorb oxygen, very much more than upon its preparation; by that I mean the number of grains used, or the amount of acid. Of course their action is varied according to strength; but it is the particular developing power of the iron that is wanted to suit the state of the collodion and bath. Nearly as much change can be made in the character of the picture, according to the kind of iron used, as there is in the collodion; this is quite irrespective of the number of grains or amount of acid. It is highly important to suit the developing power of the iron to the state of bath and collodion; for if it develops too quick for the collodion, the pictures will be hard. Every kind of iron can be kept ready by having small bottles quite full, with good corks; in this way it will keep indefinitely. Mix the two extreme irons according to the result required. Iron solution left to peroxidize is not near so good as when it is made at once by heat. If a bottle full of perfectly plain protosulphate of iron be put in the light, although the stopper is quite air-tight, and no seeming change takes place in it, yet, after having been in the light for a month, when the glacial acid is added to it, it will instantly absorb oxygen, and completely fail to develop a picture worth anything. When methylated alcohol is used for the development, it is often in itself alkaline, therefore needs no alkali added to it.

(To be continued.)

## DRY-PLATE PHOTOGRAPHY.

BY S. BEVERLEY.\*

HAVING promised you a paper on dry-plate photography, you may naturally expect to hear something of the different dry processes in general use; but I may as well confess at the outset that my experience with dry plates has been confined to the collodio-albumen process (England's method). I have, however, no doubt that any of the recognized dry processes will do quite as well; but for the same reason that some of you prefer the wet process to the dry (because you are used to it), I prefer England's method to any other for out-door work, and I would advise those of you who intend to try dry plates to consider which is the simplest and the best, and then get every requisite for that process before you begin. Prepare the plates carefully, being sure you omit nothing. You should, before exposing, let the plates be thoroughly dry, or they are sure to develop unevenly, and you might blame the process. I believe that many persons give up dry plates on account of the failures they have at the commencement, through nothing but lack of patience. Being used to taking a negative in ten minutes, from coating the plate to finishing, they do not know how to wait until a plate dries; on having done so, they hurry through the development, make their pictures hard, and then complain that they cannot get the same harmony, the same softness, combined with brilliance and vigour, that they can with wet plates. We should be inclined to ask: Why not? If you under-expose or under-develop a wet plate, you get a hard picture, or one without detail, or both; you can get nothing worse with dry plates. If you very much over-expose and over-develop a wet plate, you do not get brilliant prints; it is only the same with dry plates; and as the development of dry plates is slower and more under control than wet-plate development is, if a person fails with dry plates he is more at fault than if he fails with wet plates. Patience is a virtue that every photographer must possess, and if any of you should fail to get good results when commencing dry plates, please remember, or try to do so, the numberless

times you failed when commencing with wet plates; and I can assure you, if you persevere, you are sure to succeed.
